A JOURNAL OF ART, CIVIL ENGINEERING & BUILDING.

THE WEEK.

THE annual report of the Royal Society of Antiquaries of Ireland refers to the untimely death of Mr. JOHN L. ROBINSON, architect, who was one of the most useful and active members of the Society. On the formation of the committee for the purpose of carrying out the photographic survey of the antiquities of Ireland, Mr. ROBINSON consented to act as hon. curator, and in connection with this undertaking his loss will be most severely felt. The Council are, however, making arrangements for carrying on the work. It is announced that on Whit-Monday Kilkenny will be visited, and on the following days the city and county of Waterford. For some years past it has been the wish of the Council to hold a meeting in Connaught. It is now proposed to make Galway the headquarters for the summer meeting and excursion in the first week of August, and to visit the three Islands of Aran. As it would be necessary to charter a large passenger steamer from Belfast, with suitable sleeping accommodation, about a hundred members would have to join in the excursion. They would have the opportunity of visiting the Western Islands, including Tory Island, Inismurray, Clare Island, High Island, as well as the Aran Islands. This trip would occupy from Tuesday to Saturday, leaving Belfast on Tuesday and arriving at Galway on Saturday afternoon. The cost for each member, including steamer, sleeping berth and board, would be 6*l.* 10*s.* It is proposed to hold the fourth quarterly meeting of the Society in Wexford, in September, with three day excursions in the county, and there will be some day excursions from Dublin, including a trip to the Loughcrew Hills in June. Visitors to Ireland who can take part in the outdoor work of the Society will have this year opportunities of seeing pleasant places in good company.

THE jury for examining the plans of the projected new Ghizeh Museum building is composed of FAKHRY PASHA, Minister of Public Works (president), MUSTAPHA FEHMY PASHA, TIGRANE PASHA, YACOB ARTIN PASHA, Sir ELWIN PALMER, Messrs. GARSTIN, DE MORGAN, BARVIS, who form the present Museum committee, and the six Commissioners of the Public Debt. It is intended also to request the assistance of four architects of European eminence, to whom all the competing plans would be first submitted. Mr. SOMERS CLARKE will probably be one of the four. The 1st of March next is the latest date on which plans will be received by Government.

It must require unusual courage for a town councillor to become a member of the Library and Arts Committee of the Liverpool Committee. Every recommendation of that committee is treated differently to those which emanate from other departments, and money is granted most grudgingly. The latest case arose on Wednesday. It was proposed to purchase a picture of an idyllic kind by Mr. ARTHUR WARDLE, a local artist, the price being only 80*l.* The grant of the money was opposed on the ground that only first-class works should be acquired. There is no use in having an art committee unless respect is given to the

judgment of the members, and hitherto in Liverpool the recommendations, although they did not always find favour with the Council, were of a kind which were approved among amateurs. It would be absurd to limit the books in a public library to the epics in prose and verse, and in a picture gallery various needs must also be considered. The Liverpool aldermen and councillors, who insist on the rejection of all paintings which are not masterpieces, are, we suppose, gentlemen of most refined taste, but they ought to remember that all the citizens are not equally endowed by nature and culture.

WE regret to announce the death of Mr. HAROLD SWAINSON, who was joint author with Mr. W. R. LETHABY of the interesting volume, "The Church of Sancta Sophia, Constantinople; a Study of Byzantine Building," which we recently reviewed. The parts which were derived or translated from classic or foreign languages were mainly his work. It is pointed out in the book that the constructive methods which were employed in JUSTINIAN'S church are not obsolete, and Mr. SWAINSON was engaged in a further study of the continuance of traditional processes among the Coptic and Arab builders at the time of his death, which occurred suddenly on December 31. He had only reached his twenty-sixth year.

THE small but most convenient diary and collection of tables for architects which Messrs. SPRAGUE & Co. have issued for several years, and which has become a sort of *vade mecum* in the profession, appears in an improved form. All the tables and memoranda have been revised by Mr. F. R. FARROW, and information has been added without an increase of bulk. The little book is a model of condensation, and its utility is unquestionable.

AN important judgment has been given by Mr. Sheriff SPENS, in Glasgow, which suggests the peculiarity of Scottish law about party walls or mean gables. A brick wall 23 inches thick separated two properties, and therefore occupied 11½ inches of each property. It was proposed to erect a building four storeys, or 51 feet, high on the top of the wall. The owners on the opposite side objected, and litigation began. The Sheriff declares that the plaintiffs have no right to use the wall for the purposes proposed. He grounds his opinion mainly on a decision by Lord CLIFFORD, who held that where there is no room for implied contract and implied consent the builder of a tenement must build its gable and all entirely upon his own ground unless he gets the consent of his neighbour. In this opinion Lord GIFFORD, Lord Justice-Clerk MONCRIEFF and Lord NEAVES concurred. The Sheriff considered that to raise a structure 51 feet high would make a material difference in the light of the premises adjoining, and accordingly dismissed the action. The question arose as to whether the wall was to be regarded as a mean gable or a mean division wall, and all the architects and builders in Scotland, as well as the lawyers, would be divided in opinion about the answer to be given; but the Sheriff made short work of so subtle a pleint, for he said it was indifferent to him what name was given to the wall.

G. E. STREET AS A DRAUGHTSMAN.

TO understand the perspective drawings of the late Mr. STREET, R.A., it would be well to begin with a consideration of some of his letters in which he introduced sketches. They would show how closely his verbal descriptions or instructions were associated with his drawings, and as one class of expression supplemented the other it was sometimes difficult to determine which had precedence

out of every bit of a building; but Mr. STREET was either too busy or too indifferent to trouble himself about anything less than general views.

We have reproduced on a small scale a few of his drawings, to enable us to ascertain whether there were any characteristics in his work sufficiently consistent to constitute a style. It will be evident, in the first place, from the engravings, that the point of view selected was always one which allowed the greater part of a building to be seen, and

HOUSE AT HOLMDALE, SURREY, 1874.

with him. The same pen and the same ink served him in his calligraphy and in his sketches; he could write and draw with equal facility. There are some architects who are admirable draughtsmen but who hate expressing their thoughts in writing, while there are others who can compose reports and long pages of communications without hesitation about words or phrases, but they are compelled to leave the necessary diagrams to be filled in by an assistant. Mr. STREET possessed a capacity for explaining clearly and with fluency his thoughts in both ways. It might be supposed he could instinctively discriminate between the representable and the non-representable things which constitute the world, and that for the former he considered figures were more suitable exponents than words.

His drawings, especially those in which he represented buildings and structures as a whole, may be said to possess a sort of descriptive character. Mr. STREET rarely attempted to appear as a pictorial artist; his aim was simply to convey an idea of his building by means of lines which he employed because they were more effective for his purpose than words. Accordingly, there is a remarkable impartiality (no other word is so apt) about his drawings. All parts are treated uniformly. We cannot see signs of his lingering over a tower or a chancel, a window or a porch, as if he felt any of them was a happy thought, a sign of inspiration or a source of peculiar pleasure to himself. On that account his drawings may appear to be deficient in artistic quality. A painter who anxiously seeks that quality never cares to represent a building thoroughly. He believes in degree and priority as well as in proportion, and accordingly he selects some part on which he confers a sort of supremacy. By so doing he allows imagination to have some chance, for those who gaze on the view will endeavour to create the whole building from it. REYNOLDS may have had the arrangement in his mind when he said, "There is in architecture, as in painting, an inferior branch of art, in which this imagination appears to have no concern." Many architectural draughtsmen act on that principle in treating proposed works. That architects also approve of the arrangement is evident from the number of views of parts of buildings which are to be seen from time to time. There is no reason why as much as possible should not be made

the arrangement on plan to be inferred. In the next place, all the main lines, although they are often fine enough to suggest the geometric definition of length without breadth,

ST. DIONIS BACKCHURCH, 1858.

are continuous and carefully ruled. It is sometimes supposed that broken lines are among the producers of picturesqueness, and that it is an advantage when a drawing appears to have been completed without much use of a T-Square. In representing old work, as in the transept aisle of York Cathedral, which is near the monument of Dean DUNCOMBE, Mr. STREET allowed himself a liberty of that kind, but it is evident he considered that precision was

have gained in effect. But as we have said already, pictorial effect was of little importance to Mr. STREET when it had to be obtained by a sacrifice of verity. His views are practically descriptions which could be offered as evidence in Courts instead of photographs. For the same reason he never made as much out of the shadows which were cast by the projections of his buildings as he might have done. Apparently he considered his purpose was served

ST. MARY'S CHURCH, SOUTHAMPTON, 1877.

required when new buildings, or anything appertaining to them, were to be represented. The gables and windows of his Surrey house suggest the *finesse* with which he endeavoured to express intricate detail on a small scale without any abridgment of length. His love of truth is also seen in the care taken to demonstrate that the walls of the buildings were masonry and of what class. If he treated some of the sides of the buildings as if they were characterless, that is, as blank spaces, his drawings would be declared to

when the variety of planes were indicated. Strong shadows are also likely to obscure detail, which was not desirable to his mind. His figures were almost insignificant, but generally he was indifferent to their use as units of scale. His trees and foregrounds were always of the simplest. When, as in the view of the Brightwaltham Church, the lychgate and school are introduced by a few careless scratches, we may be sure they formed no part of his commission.

In spite of the restraints he imposed on himself and

the simplicity of his aims, his drawings have a sort of vital quality. They are as characteristic of the author as his handwriting. This fact will be evident by a comparison of the reductions of his drawings with one from a fine lithograph which was copied from a drawing by Mr. STREET, representing a proposed church in Fenchurch Street. It is evident that the lithographer drew all the lines with painstaking accuracy, but somehow they have not the "go" which is visible in the drawings, although to the multitude, on account of their animation, the latter may seem to be less perfect. If the church represented had been carried

out, the City would have acquired something that possessed novelty no less than beauty.

If in the architectural lines Mr. STREET tried to be as exact as the scale of the drawing would allow, he found compensation in dealing with accessories. Writing masters of the old school used to exhibit wonderful productions which were declared to be created by a single stroke of the pen. Mr. STREET's trees often seemed to be examples struck off in rivalry with the ornamental caligraphy. The outline of a group of trees would be completed without the pen being raised from the paper, and a few zigzag

MONUMENT OF DEAN DUNCOMBE, 1881.

touches would then be put in to express the remaining greenery. His zigzags were of great utility to him, for they served many purposes. They were made to suggest shadows, masonry, foregrounds, as well as vegetation. We suppose Mr. STREET considered they produced an effect of continuity, and they answer as well as repetitions of colour to unite different parts of his drawings. Occasionally they were introduced to make up his cloud effects, but TURNER himself would be unable to express the phenomena of the "azured vault" if he were restricted to pen and ink. The free strokes which Mr. STREET employed around his buildings had the advantage of giving more effect to the architectural lines which formed a contrast with them. As all his lines were fine, it was not easy to make his drawings appear vigorous, yet they have more effect of that sort than many drawings which were made up of far thicker lines. The reason is that every line of Mr. STREET's was drawn

writing a word or two about drawings of another sort. Mr. STREET's working drawings were models of clearness, although they were not always free from altered lines, for he was painfully anxious about the accuracy of details, and he was competent to design for every kind of material that was employed in one of his buildings. His manner of sketching might be called peculiar, for it was, as it were, a language or shorthand which was more significant to him than it could be to a stranger. In his masterly book on "Architectural Drawing" Mr. R. PHENÉ SPIERS gives the following account of the process:—

The most indefatigable sketcher of modern times (the late Mr. George Edmund Street, R.A.) used a book measuring 8 inches by 6½ inches, and invariably extended his drawing across the two pages. Long experience, possibly, enabled him to so place his drawing that the fold in the middle did not materially interfere either with the effect of the drawing as a whole, or the proper vanishing of his perspective lines. As he always drew freehand when sketching out of doors, *i.e.* without

CHURCH AT BRIGHTWALTHAM, WANTAGE, 1868.

with decision, and that the thinnest was expressive of some definite purpose. The success of his method of representing buildings is perhaps more evident from a comparison of the translated or engraved examples from his sketches, which appear in his books on Spain and Italy, with those from sketches by other artists. The superiority of Mr. STREET's will be evident at a glance, for in them we see that nothing was sacrificed for the sake of effect. From his mastery of every detail he was able to insure accuracy of form in a drawing, however small.

Mr. STREET's style can be considered as having as much correspondence with that "style coulant" which is prized in France as can arise between lines and words. His perspectives do not appear laboured, and they might be taken for hasty productions. But they could not be completed except by a hand that was delicate, assured and flexible, and guided by a mind that saw too clearly to become confused. Mr. STREET's perspectives corresponded with his powers and his knowledge, and in consequence they are not easily to be imitated.

It would be unwise to conclude this article without

the use of rule or compass, he contented himself with drawing only the leading lines, whether straight or curved, as cornices, string-courses, vertical shafts or arch mouldings, simply indicating the starting-point of the others, and leaving it to the eye to supply their continuation, the result being that the sketch is not overlaid; there is not a line in his drawings which could be spared, and no more is indicated than absolutely necessary to convey a full idea of the feature portrayed. Mr. Street not only discarded the use of instruments, but of indiarubber as well; the greatest care, therefore, had to be taken in the setting out of his sketch, and long practice and accuracy of eye enabled him to preserve the scale throughout in his drawings; his great knowledge of detail of every kind of Gothic work allowed him to grasp at once the characteristics of any feature, and to delineate it in the fewest possible lines. In all cases, when easily obtainable, Mr. Street noted the principal dimensions of the features he drew, whether sketched in perspective or geometrically.

It was Mr. STREET's conviction that the pen was the most fitting aid in the representation of buildings of a Mediæval type. His treatment of the style might have been altered if he made use of a pencil and colour. He had no desire to change his manner, but it must be said that the sight of a good coloured drawing of one of his buildings gave him pleasure that was surprising.

NEW EDINBURGH: SKYLINE.

By E. F. C. CLARKE.

TO those who, like the writer, knew the wonderful city and town of Edinburgh some thirty years ago, the growth of this picturesque city southwards, towards the Braid and Pentland Hills, cannot fail to prove a source of sincere admiration, and to the jaded eye of the wearied designer it is a really refreshing oasis in the general desert of confusion.

The great glacial or volcanic ridge, rising at Holyrood near the bottom of Canongate, crowned with towering grey gables and roofs, and culminating in the superb mass of the Castle Rock, with its bastions and ramparts grey in mist, smoke, sunshine and shadow, is known to all visitors who have eyes to see. Princes Street, commonplace and vulgar in itself, but noble by reason of what it looks upon—this street, with its wide valley underlying the vast mass of picturesque forms that soar into fine grey mist by day, and melt into countless clusters of twinkling lights by night—

the effect they were destined, by sheer accident as far as they were concerned, to produce. In truth it must be owned that much of the building about this region, viewed critically, is decidedly commonplace. The pseudo Italian debased Renaissance, the patent Scottish Baronial housemaid's turret, the playful and aggressive pinnacle—these are jumbled together in a manner which on flat ground would be decidedly distressing, and productive of nought but melancholy and depressing reflection. As a matter of fact—and skyline born of natural conformation of ground is the text of this brief notice—the general result of this new development of modern Edinburgh as seen against an early morning sky, or it may be a storm-cloud or a summer moon-rise, is simply a revelation. The whole composition is unmistakably beautiful and well worthy the artist's pencil. It is a perfect dream of finely-drawn grey mass against light, a subject that TURNER would have prized and noted and used on the instant.

Modern Edinburgh, like most other towns, has its quaint and curious incongruities. People are to be found who would dare to assail the gruesome grey squalor of a

defies Europe to find its peer. It may be at once assumed that varied contour of ground, combined with that individual effort that is characteristic of building in a free country, form the basis of most that is acceptable, and of much that is really beautiful in that one most important feature of architecture as viewed in the aggregate—"skyline," man's creation cutting the eternal sky, and being for ever ennobled by its association with the far beyond.

The extension of Edinburgh on its southward slopes from the great ridge is, curiously, a veritable second edition as it were of the wonders of the "Old Town," though different in character. The so-called "New Town," sloping down towards Granton and Leith, is widely known for its melancholy, dreary monotony, its precise sterility, and its appalling and unassailable respectability. But in the subject before us, the utilising of the falling ground dominating the region known as the Meadows and Bruntsfield Links, nature has, by reason of the undulation of the ground and its inevitable complement of clustering roofs and harmonious incidence against the luminous sky, come to the rescue of builders who can have thought but little of

Queen Street by the introduction of a palpably imported pink Gothic doll's-house, an erection that not only looks sorry for itself, but seems to wish it had not come there. The unrivalled and beautifully-kept Princes Street Gardens, in the valley between the Old and New Towns, are adorned with a huge cast-metal fountain (made in Germany?), on which may be seen, on days when the water company is in complacent humour, some twenty-four young ladies, all sea-sick at the same time. This fountain is a singularly emphatic triumph of inept, irresponsible vulgarity. Princes Street has long been "up" for the grand installation of electric light, which will doubtless, by its blatant nightly flare, extinguish at nightfall one of Edinburgh's most startling graces—that dreamy flicker of myriad points of burnished gold in the countless windows of the majestic old grey town across the valley. The scheme formulated some thirty years ago for piercing and probing the huge masses of sixteenth-century buildings in the Old Town, those lofty piles of endlessly beautiful crow-stepped and turreted structures that, in solemn and sombre grey, stood out so mysteriously against the ever-changing northern sky—those

plague-stricken fever-dens that were no longer habitable even by the waifs and strays that could exist under conditions quite unmentionable to polite ears—this scheme has been carried out, and, to the honour of the architects concerned in the work be it said, without materially impairing the general mystery and grandeur of the town called by the greatest of Scotsmen "the grey metropolis of the North." SCOTT has been blamed by pedants for this most happy, most apt, and most artistic description of a city that is

to the Edinburghians, and a terrible example to people who desire to tell transparent lies by the degradation of architecture. It is the artificial "ruin" of the suburban "rockery," and an eyesore to all beholders, even far out at sea. It was to have been a second Parthenon, presumably for sea gulls, but the funds failed, and probably the persons engaged in the ridiculous effort to create a second Acropolis became a little ashamed of the business, though had they possessed any feeling whatever for the credit of their town they would

always, and in every varied light of nature, sympathetically and mysteriously grey. As an instance of the undoubted success and fidelity to tradition with which the improvements in the Old Town have been effected, let anyone look from the east end of Princes Street straight up the North Bridge, and he will see a nobility of mass, contour and soaring skyline which will convince him that modern sanitary improvement is not incompatible with the preservation of true sentiment and real architectural dignity.

doubtless have changed their minds and carted away the stones of this hideous sham.

The region of ALLAN RAMSEY'S house—that superb consummation point of nature's design for the city of Edinburgh—where the great ridge of gabled houses abuts upon the Castle Esplanade, bristles with new red-tiled roofs and Queen Anne innovations, albeit with harmonious effect as seen towering above the green Castle slopes, and with noble skyline, thanks mainly to noble groundline.

This vista, striking the distant sky across the ridge that is the initial cause and origin of the grandeur of this unique town, is a study in itself, and is a mighty instance of what can be done in improving streets and dwellings when the keynote of the composition is touched by nature herself, and is faithfully regarded and followed by those on whose shoulders lies the responsibility of completing and ennobling the theme.

The "National Monument" on the Calton Hill still remains a disfigurement to the general skyline—a reproach

But new Edinburgh, as seen from the Bruntsfield Links in the soft light of an autumn afternoon, or at sun or moonrise, is something to be enjoyed, studied and thought about, for it is surely here that a most vaunted and undoubtedly a unique city has made an extension of its borders, that has not marred but has rather enhanced and emphasised its ancient glory as one of the most charming of creations, which cannot be once visited without receiving a lifelong impression

HISTORY OF THE TOWER BRIDGE.*

AT the time when the subject of the Tower Bridge was under consideration and there was a risk of narrowing it to a mere question of providing an additional roadway, regardless of the injury to the traffic on the river, we endeavoured to suggest the relations of the case and wrote as follows:—

It is recorded that when James I. threatened to punish the citizens of London by the removal of himself and his court to some other city, the Lord Mayor calmly informed the king of the hope of the citizens that His Majesty would leave them the Thames. So long as the river remained the people of London believed that they might endure the loss of even the Solomon of the West. Since that time much has been done by means of railways and improved roads to facilitate the intercourse of nations and to promote commerce, but the Thames is still what it was in the days of King James, the link by which London is united with the rest of the world. If, as Sir John Herschel says, "London is the centre of the terrene globe," that position is due to the possession of a navigable channel. What other city can show such a proof of international trade as may be witnessed every day in the year between London Bridge and Blackwall?

The supremacy of London in commerce is in a great measure attributed to the navigability of the river, and in dealing with the Thames this fact should be never overlooked. While everyone admits the advantage of unimpeded communication between the parts of the Metropolis on both sides of the river, it should also be remembered that an advantage of the kind would be dearly purchased if to secure it impediments were raised to interrupt the traffic on the water. The local requirements of Whitechapel and Bermondsey should never be allowed to override the general interest of the City (which is also the interest of England), and although it would be well for carts from Shoreditch to reach the Old Kent Road expeditiously, the gain in time would hardly compensate for the loss that is inevitable if commercial arrangements which have taken centuries to mature should be disturbed or destroyed.

When, for example, it is proposed to erect a bridge with a massive pier in the very middle of the waterway, or a bridge of a height that will prevent many of the vessels that trade with London from passing under it, or a bridge on so ingenious a principle that there is risk of the intricate machinery becoming disarranged in the opening or closing, it is evident that in every one of those cases there is a certainty of interference with the traffic of the Thames, and the trade of the port will in consequence be sacrificed to local interests. On the other hand, a fixed bridge at a high elevation above the river would involve local inconvenience, for it must be costly, and unless the approaches are carried for a great distance inwards, the gradients will be steep and involve a loss of tractive power.

If the foregoing assumptions are correct, it is evident that the question of constructing a bridge over the Thames below London Bridge is one in which compromise is demanded if there is to be a satisfactory solution. Something must be abated by all parties, by the representatives of land traffic as well as by the riverside proprietors. It is physically impossible to have a bridge with easy gradients for land traffic and which will be also clear above the highest masts, or one on a low level which shall still be equally convenient for ships and waggons; and the most prudent course will be to construct a bridge on a principle that will give a minimum of inconvenience while allowing of easy gradients and a capacious waterway.

A great many inhabitants of London were of opinion that there was opposition between metropolitan trade and the shipping industry. It seemed to them that, as the Metropolis grew, London Bridge should not be the last means of communication between two important regions, and that little harm would arise if vessels and large steamers were compelled to keep to a lower reach. There were others who believed that the trade which lies immediately to the east of London Bridge could be conducted by means of barges at an expense which would be insignificant if compared with the advantages arising from the existence of another bridge lower down, as accessible as London Bridge.

There were not only the powerful, if selfish, interests of metropolitan traders against an adequate solution of the problem, but the Metropolitan Board of Works were manœuvring to impede the action of the Corporation in the creation of such a bridge as was needed. The Board's engineer in 1878 prepared a design which "ignored or showed a thorough disregard of all the evidence, views, wishes and interests of the wharfingers and of shipowners trading between the site of the proposed bridge and London Bridge." Unfortunately the same sort of dog-in-the-manger

policy has been inherited by the London County Council, and the discreditable tactics by which the Tower Bridge is left without suitable approaches are evidence of the strength of the obstructive spirit in Spring Gardens. The Corporation, however, continued to study the subject in spite of the obstacles created by the Board. There were two classes of solutions, viz. a high-level bridge which would allow ships to pass under it, but which would need long approaches, or an opening bridge. In 1878 the City architect, the late Sir HORACE JONES, submitted a design for a bridge on the bascule principle, which had not been applied previously over so large a waterway. His bridge allowed of a low-level roadway for ordinary traffic. But, as happens with the majority of swing, rolling, sliding and other opening bridges, pedestrian traffic as well as traffic on wheels would have to be suspended while the bascules were raised to allow ships to pass. The principle was novel in this country. The Corporation hesitated, and the architect's design was set aside for a time.

The discontent which arose mainly from the inadequacy of London Bridge increased every year. At the end of 1883 the Board of Works, taking advantage of the state of feeling on the subject, lodged their Thames Crossing Bill. A Bill for a Tower Bridge was also lodged by a company, and one relating to steam ferries by the Corporation. The recommendation of the Parliamentary Committee that considered the Bills, in July 1884, was that a subway should be constructed at or near Shadwell, and a low-level bridge at Little Tower Hill, with two openings, each about 100 feet wide, to be spanned by a pivot swing-bridge. The Corporation loyally endeavoured to carry out the committee's report. A deputation at once visited Belgium and Holland to consider the various types of swing-bridges. Reports, designs and estimates were afterwards prepared. By the end of the year the former proposal of the City architect appeared more feasible, and accordingly a Bill was lodged seeking powers for the construction of the Tower Bridge. HORACE JONES had prepared three designs; two were for a swing-bridge, the difference between them being in the character of the towers, while the third, which he preferred, was for a bascule bridge. The principal opponents of the Bill were the wharfingers, who were apprehensive about their interests while the bridge was in progress. Arrangements to satisfy them were agreed on, and the Bill was passed on August 14, 1885. Nine months afterwards the works were commenced, the contract for the foundations, with the piers and abutments for a height of 4 feet, having been taken by Mr. J. JACKSON, of Westminster, who is about to receive the well-deserved distinction of knighthood. The amount was £131,344.

The design for the Britannia Bridge over the Menai Straits would never have received the sanction of Parliament if STEPHENSON had not introduced several chains to uphold the rectangular tubes. The design which HORACE JONES prepared appeared to be intended to overcome a fear of that kind, as if some Parliamentary engineer had gone over the drawings. The bascules were tied by chains to a great semicircular arch, which was in its turn tied to the towers, and the chains were finally carried to the ground. Counsel could declare to the committee that the Tower Bridge possessed all the stability that a combination of girders, arches, suspension-bridges and towers could confer. Afterwards the arch was removed, an upper footway for pedestrians was introduced, but the design submitted to Parliament displayed a more cumbrous structure than now crosses the Thames.

Sir HORACE JONES evidently desired to impart more architectural character to the Tower Bridge than is visible in the bridges which are of later date than the Waterloo Bridge. His piers were not only made to resemble feudal keeps, in order to correspond with the Tower of London, but they were to be able to withstand all the direct and indirect strains of the chains, arch and girders, with their loads. When the limited area fixed for each pier (185 feet by 70 feet) by the Conservators of the Thames is remembered, it may be doubted whether they possessed the mass which would be requisite to counteract such great strains. The towers would no doubt serve to sustain a Mediæval drawbridge with its load of knights, squires and men-at-arms; but the unromantic traffic of London is heavier than a company of plumed warriors in armour.

* *History of the Tower Bridge and of Other Bridges Over the Thames Built by the Corporation of London*, including an Account of the Bridge House Trust from the Twelfth Century, based on the Records of the Bridge House Estates Committee, by Charles Welch, F.S.A., Librarian to the Corporation of London, with a Description of the Tower Bridge by J. Wolfe Barry, C.B., M.Inst.C.E., Engineer to the Bridge, and an Introduction by the Rev. Canon Benham, B.D., F.S.A. Prepared under the direction of the Bridge House Estates Committee (Sir Albert J. Altman, chairman). Smith, Elder & Co.

Mr. WOLFE BARRY, who was associated with the City architect during the passage of the Bill through Parliament, and who has had the sole responsibility for the erection of the bridge, was compelled to take a prosaic view of the requirements. He dare not rely on the masonry for affording operative strength, so he made the best of the case by allowing it an ornamental office, viz. to screen the iron and steel which are the efficient agents. Mr. WOLFE BARRY offers the following explanation of the system he adopted:—

It became apparent that it would not be possible to support the weight of the bridge on towers wholly of masonry, as in the first designs, unless they were made of great size and unnecessary weight. It was consequently requisite that the main supports should be of iron or steel, which could, however, be surmounted by masonry so as to retain the architectural character of the whole structure.

It was clear that in any event a large part of the steelwork of the towers must be enclosed in some material, for the moving quadrants project upwards some 40 feet from the level of the roadway, while the stairs and lifts also required protection from the weather. It thus became a question of surrounding the towers either with cast-iron panelling or with stone, and eventually a granite facing with Portland stone dressings was adopted.

Esthetically speaking, stone appears better than cast-iron, which would equally hide the constructive features, and, practically speaking, it is also better when it is considered that there is no mode so satisfactory for preserving iron or steel from corrosion as embedding it in brickwork, concrete, or masonry. Careful provision has been made in all parts for expansion and contraction of the two materials, and

a distance of 148 feet 8 inches within the pier. Mr. WOLFE BARRY gives ample information about their construction. Each of the bascule girders has a total length of 162 feet 3 inches; the pivot on which it turns is 112 feet 9 inches from one end. The weight of the longer arm is 424 tons and of the shorter 621 tons. The opening span can be moved from a horizontal to a vertical position in one and a half minutes, and a similar time is required for stopping the road traffic and clearing the bridge. The ascent or descent of a lift in the tower through a height of 110 feet occupies one and a half minutes. It would be impossible to have so much expedition without the perfected hydraulic machinery which is associated with the name of Lord ARMSTRONG. The economy of water-power is suggested by the following passage:—

The pumps are on the Surrey side of the river, and are placed in arches under the south approach. The high-pressure water is brought thence in pipes along the Surrey fixed span, up the Surrey tower, across the high-level footbridge and down the Middlesex tower. Return pipes convey the water—when it has exerted its pressure at the hydraulic engines, which are fixed below the footway on each pier—back again to the pumps at the steam-engines, where it is subjected to pressure, and made ready for work again.

There is so much motion that the Tower Bridge may be regarded as a great machine, and it presents dynamic as well as static problems to all who care to study them.

ERECTION OF TOWERS AND CANTILEVERS.

though there have been great extremes of heat and cold since the masonry has been built, no effects resulting from any difference of temperature have been observed.

It is to be feared some purists will say that the lamp of truth has been sadly neglected in this combination of materials, and that the architects of Classical or Mediæval times would not have sanctioned such an arrangement as a complex structure of steel surrounded by stone.

One reason may be that the architects of those ages did not know much about iron or steel. Perhaps if they had been acquainted with their capabilities they might have been as ready to employ them as they were to back up stone-faced walls with brick and to hide the constructive features of their buildings, as Sir Christopher Wren did when he used a brick cone to support the internal and external domes of St. Paul's.

However all this may be, "needs must when Parliament drives," and if the appearance of the Tower Bridge is approved, we may forget that the towers have skeletons as much concealed as that of the human body, of which we do not think when we contemplate examples of manly or feminine beauty.

The piers are also "very complex structures," for they have not only to sustain the weights of the towers and girders, but they cannot have solidity. There are hollow chambers in them to allow the motion of the bascules, and others for hydraulic accumulators, hydraulic engines, &c. On one line of section where the length of the pier is 185 feet, it is possible to walk continuously through

The construction of the bridge was as fine an example of organisation as can be discovered in the history of English contracting. The size of the staging in the river was limited by the Act, and the Conservators of the Thames insisted on a clear waterway of 160 feet in width. It was, therefore, impossible to construct more than one pier at a time, and there could be only one staging at a time, of the full width required for building the piers.

It will be observed from one of the views that each tower has four wrought-steel pillars which are octagonal on plan. They are united by horizontal girders, which serve to carry landings, floors, &c., and stiffened by diagonal bracing. On the tops of the pillars are rollers, which allow the chains passing over them to have such motion as may arise from expansion or contraction, or the unequal distribution of loads on the roadway. The rollers are excellently arranged in order to avoid the possibility of a concentration of weight on one or two of them. The chains are not like those used in suspension bridges; "they are, in fact, chains stiffened to prevent deflection, and the object of the form is to distribute the local loads due to passing traffic, which, in the case of an ordinary suspension bridge, depress each part of the chain as the load passes, and consequently distort the platform of the bridge. By making the chain, as

it were, double, and bracing it with iron triangulations, these local deflections are avoided."

The high-level bridges for foot passengers at top of structure are also interesting on account of the manner of erecting them. The span of each is 230 feet, but owing to restriction of keeping an open waterway it was necessary

the work to the most experienced contractors that could be discovered, and allowed the engineer the fullest authority. If the amateurs of Spring Gardens could have got hold of such an undertaking a very different result must have followed, for the whole affair would be manipulated for the glorification of a party of the members, and to bring odium

ERECTION OF MAIN CHAINS.—I.

to dispense with scaffolding. "These bridges," says Mr. WOLFE BARRY, "are cantilevers for a distance from each tower of 55 feet, and are girders for the remaining space of 120 feet between the ends of the cantilevers. They were erected, however, by temporary expedients entirely as cantilevers, piece by piece from the tops of the towers and with-

on some class or other of the inhabitants of the Metropolis. There is cause for congratulation that instead of a costly fiasco like the economical experiments in construction of the Council, London has gained a bridge of which every inhabitant should be proud, and one that, like London Bridge, Southwark Bridge, Blackfriars Bridge and the

ERECTION OF MAIN CHAINS.—II.

out scaffolding from below, for the whole of the semi-span of 115 feet, till they met over the centre of the river." The steelwork was carried out by Sir WILLIAM ARROL & Co., and is no less creditable to them than the more extensive work at the Forth Bridge.

The success of the bridge is owing to the fact that the Corporation, according to their usual practice, entrusted

Holborn Viaduct, is a memorial of the prudent government of the Corporation of London. Mr. WELCH'S history contains much that is most interesting about the earlier engineering works of the City, but we are compelled to postpone our notice of that part until next week. Meanwhile, we can say that the "History of the Tower Bridge" is as fascinating for the antiquary as for the engineer.

PRESERVATION OF ANCIENT PAINTINGS.*

Translated from the Italian by JOHN HEBB.

IN the endeavour to preserve ancient paintings one is confronted by a dilemma which, although it may assume various forms, is always the same—whether to leave them to perish of themselves, or to hand over this important portion of the heritage of the nation to the power of the restorer.

But now restorers, with certain exceptions, are unfortunately quite empirical, entirely devoid of the most elementary knowledge of chemistry, distinctly disposed to apply their formulas to differing cases and conditions, and so intent on occupying themselves above all things with the appearance of the restoration at the moment of completion, as to justify the apprehension which every connoisseur of ancient pictorial art experiences when paintings are placed in their hands.

Nowadays we no longer restore, we preserve, and it certainly was a great step in advance to have induced the conviction that the authenticity of paintings, as well as of every other work of art, is a fundamental condition of their intrinsic value; that the tone of paintings by time attests their antiquity as well as adding a harmony of a more elevated order than the hand of man alone can bestow, at the same time contributing to and differentiating the methods peculiar to every age and every great school of painting.

We begin, on the other hand, to tread upon unknown or at least uncertain ground, when we attempt to choose the most appropriate means for the preservation of paintings, if our choice be made under the influence of an empiricism discordant in every particular except its superficiality, or in the insufficient duration of experiments on the methods to be adopted. This superficial empiricism occasions that blackening which is generally characteristic of the work of all restorers, and the final recognition on the part of experts that ancient paintings, when treated by various methods opposed to one another, are frequently ruined.

When an ancient painting is in danger of being lost, by the colour drying and becoming detached, a repairer is called in, who is instructed, for instance, to confine himself to fixing the colour, that is to say, to carry into effect the most severe precepts for the preservation of ancient buildings; but here begins an entirely new series of dangers to which the painting is exposed through the means adopted to repair it. It is too often the case that on this account many ancient paintings are entirely ruined, or their old defects reappear with accelerated rapidity, while other paintings are destroyed by the loss of the characteristic qualities attributable to the nature of the materials used by the artist, or are exposed to periodic repetitions of partial obscuration and other evils, for which it is necessary to provide a further remedy in addition to that which would have at first sufficed.

The inexhaustible and varying recipes of restorers have converted frescoes into encaustic or tempera paintings, caused dry distemper to disappear under greasy varnish, and mummified at other times oil-paintings with resinous gums. Sometimes the glue laid on a mural painting will give cohesion to the colour for a year or so, but this afterwards hardens, and splits off in a myriad of minute scales, which curl up and fall like autumn leaves, leaving the plastering bare; sometimes the mysterious recipes lead to disastrous and unexpected results, induced by mixtures which even the restorer himself was unacquainted with, applied to paintings of which he had not studied the nature, or under conditions which he was not in a position to investigate or appreciate.

All this demonstrates the necessity and urgency of regulating the work of restorers or repairers of ancient paintings; but in order to so regulate it is necessary to collect and tabulate the result of investigations made up to the present time on the handling and technique of particular kinds of painting, the alterations they may have undergone and the mischiefs occasioned in respect of their material composition by atmospheric influences or accidental injury; and, in addition, as to the means best adapted to repair the different kinds of damage occasioned to ancient paintings and to remove or diminish the cause of further mischief.

The following prize competition has for its object the arrangement and perfecting of the researches made up to now on the various methods of painting, in order that they may serve as a preliminary for further investigations.

The Minister of Public Education, with the view of procuring the necessary materials for the study of the principal problems relating to the preservation of ancient paintings, has instituted a competition for an essay on the technique of painting, setting out and completing as far as possible the useful results of the inquiries made up to date as to the materials and methods used in the production of the various kinds of painting, including fresco, encaustic, distemper, oil-painting on wood panels, on canvas, &c.

* Extract from the Italian Official Gazette, Office of Public Education, Department for Ancient Buildings and Art Schools.

The essays, which should be sent in not later than June 30, 1895, will be adjudicated upon by the Central Commission of Fine Art, assisted in certain circumstances by specialists capable of judging of their scientific value.

The author of the selected manuscript will receive a prize of 3,000 lire (120*l.* sterling).

G. BACCELLI,

The Minister.

Rome: November 1, 1894.

AN ADORNMENT LEAGUE.

THE Americans have leagues of many kinds, good, bad and indifferent, but it may be doubted if there is one that is better worth imitating than the League for the Adornment of the city of Chicago, of which the following are the rules:—

Article I.—The name of this organisation shall be the "Chicago Municipal Improvement League."

Article II.—The purpose of this League shall be to secure for our city such an arrangement, design and adornment of our public buildings and grounds, streets, boulevards and other public works as shall most contribute to the convenience and enjoyment of the public, stimulate an appreciation of art, and give to the city a fixed expression of its greatness.

Article III.—This League shall be a union of committees, of three each, elected or appointed by such organisations interested in the above objects as shall respond to the invitation of this League. The following organisations are represented in the formation of this League and are hereby invited to continue their co-operation by making their committees standing committees for this purpose, viz. The Illinois Chapter of the American Institute of Architects, Western Society of Engineers, Chicago Society of Artists, Chicago Real Estate Board, Chicago Builders and Traders' Exchange and the Civic Federation of Chicago. Other organisations may be invited to co-operate with this League by a two-thirds vote of the whole number of members.

Article IV.—Each committee of three, appointed by a co-operating organisation, shall be a standing committee of this League on the subjects that come within the scope of the organisation which it represents. Each committee will serve as a means of communication between this League and the organisation which it represents. No action of this League is to be binding in any way upon the co-operating organisations, but is to be advisory only.

Each committee shall have a chairman elected by itself or the organisation appointing it.

Article V.—The chairmen of the several standing committees shall constitute the Board of Directors.

Article VI.—The following officers shall be elected by the Board of Directors from their own number—a president, vice-president, a secretary and a treasurer.

Article VII.—All officers shall be elected immediately after the annual meeting by a majority ballot vote of the directors present. Officers shall be elected for a term of one year and until their successors have qualified.

Article VIII.—It shall be the duty of the Board of Directors to have general charge of the work of the League, referring special investigations to the appropriate standing committees. All expenditure of money shall be under the control of the Board of Directors, who shall devise and carry out means for raising the necessary funds.

Article IX.—The annual meeting shall be held on the second Tuesday of November, at which time the several committees shall announce their selection of members for the Board of Directors.

Other meetings may be held on the call of the President or the Board of Directors. The President shall call a meeting on the request of any five members. Co-operating organisations are requested to appoint their committees during the month of October, so that the change of membership may take place at the annual meeting, at which time reports shall be presented by all these committees. These reports shall be sent to all co-operating organisations.

Article X.—A majority of the League or any committee shall constitute a quorum.

Article XI.—This constitution may be amended at an annual meeting without previous notice, or at a special meeting upon notice of proposed amendments at least one week in advance, by a vote of two-thirds of the total number of members.

Article XII.—The officers elected at the organisation of the League shall hold office until November, 1895.

A Roman Milestone which was found near Carlisle has been acquired for the museum of the city. It formerly stood on the Roman road leading from Luguwallium southwards to York, and bears the name of Carausius, the usurper of the Empire in Britain between 287 and 293. This is the first inscription of Carausius ever found, but his coins are common.

NOTES AND COMMENTS.

THE decoration of St. Paul's was an enterprise which for a long time was considered as never likely to be effectively undertaken until the millennium was approaching. Since the subject was mooted there never was so earnest endeavour to grapple with the difficulties as can now be witnessed. For the decoration of the choir the Chapter have become responsible, and they have found a competent director in Mr. W. B. RICHMOND. But as we pointed out when the mosaics were unveiled, the work is not of a character which can be appreciated by all people. To attain that end a scene-painter would be the most eligible artist, for he can gauge the requirements of the public and present figures which, if striking, are simple. The authorities of St. Paul's wish to have a sort of pictorial Scriptures which will need some skill in hermeneutics before they can be appreciated. They have many precedents for selecting subjects that are mysterious in their symbolism. Judging by what we have seen of the effect produced by the mosaics on ordinary visitors, we imagine that curiosity is excited, which will lead to inquiry, and that irreverence seems to be subdued. That amount of success is worth much in a time like the present. Mr. W. WOODWARD, who possesses a stock of remedies for all evils connected with building, is of opinion that the cathedral authorities are in the wrong, that "there has been a most unfortunate waste of money, and as regards the progress of English art the result is degrading in the extreme." The only proper course, according to Mr. WOODWARD, would be to apply to the artist who decorated St. Annunziata, Genoa, for a scheme. Mr. WOODWARD anticipates that the cupola would then be adorned with enriched concentric bands, and without a single figure. Marbles and mosaics would be seen in the transepts and nave, with sculpture in the parts near the eye, but the surface figure-work would be very sparse. What is proposed by Mr. WOODWARD might be most excellent, but there would be nothing ecclesiastical about it. The decoration would be a perpetuation of the secular character which the church possesses, only it would be in colour instead of a stained white, as at present. The Chapter, if enough money can be raised, will provide sermons in stones for future generations, and if they are of use in any place it ought to be in the Cathedral of London. If architecture should appear in consequence to be subservient to minor arts, the result will express the belief that prevailed in our time.

THE eighteen prizes have been awarded in the competition for the Paris International Exhibition of 1900. The three of 6,000 frs. each are obtained by MM. GIRAULT, HÉNARD, PAULIN. The four prizes of 4,000 frs. each were won by MM. LARCHE & NACHON, CASSIEN BERNARD & COUSIN, RAULIN, GAUTHIER. The winners of the five prizes of 2,000 frs. are MM. TRONCHET & REY, ESQUIÉ, TOUDOIRE & PRADETTE, BLAVETTE, SORTAIS. Finally the six prizes of 1,000 frs. are gained by MM. BONNIER, LOUVET & VARCOLLIER, MASSON-DESTOURBET, HERMANT, MEWÉS, DE TAVERNIER & THOMAS. The eighteen designs have been handed over to MM. ALFRED PICARD & BOUVARD, who will endeavour to evolve out of them a definite plan for the exhibition. They will have the assistance of a report by M. GUADET on the advantages and defects of each of the premiated designs. Whether one or more of the competitors who have gained prizes will be entrusted with the execution of the works cannot be known for about six months. The Parisians are satisfied with the competition, for the designs were suggestive of a remarkable exhibition and one which cannot be easily exhausted, for there will be buildings on both sides of the Seine, and the river is also utilised. As was anticipated, the majority of the competitors were in favour of retaining the Eiffel Tower.

THE science of acoustics is obscure, and its application to buildings is often bewildering. An American architect, Mr. E. G. LIND, of Baltimore, has announced some empiric rules which he says were successful, although his conclusions may horrify lovers of the science from their simplicity. The Boston Music Hall, it appears, is a perfect specimen, and

the dimensions are multiples of a number that is not appreciated, viz. 13. The hall is 130 feet long, 78 feet wide and 65 feet high. Knowing the success of the Boston Hall, Mr. LIND resolved, when laying out a Masonic Temple in Baltimore, to employ the same multiple. He therefore made it 104 feet long, 91 feet wide and 39 feet high. As a concert hall it was successful, but when a lecturer appeared it was a failure, owing to its resonance. The old Steinway Hall, in New York, in which 13 was not exactly applied, for the size was 120 feet by 75 feet by 42 feet, was not a triumph. In the Concordia Hall, Baltimore, 10 was selected as the multiple, but without any acoustic advantage. Mr. LIND, having faith in odd numbers, like RORY O'MORE, resolved to try some experiments with the number 7. When he had to build a Presbyterian church in Georgia he accordingly laid it out with a length of 70 feet, a width of 63 feet and a height of 35 feet. Hundreds of divines, it appears, have borne testimony that it is not surpassed for the excellence of its acoustic qualities. In a smaller church Mr. LIND also adopted the same number, and once more he was successful. The First Presbyterian Church of Baltimore, which is also esteemed by preachers, is 70 feet long, 63 feet wide and 63 feet high. The Cincinnati Music Hall is from 1 foot to 3 feet in excess of a correct application of the number which may arise from defective rods, for it measures 402 feet in length, instead of 399 feet, 316 feet in width (315 feet), and 150 feet (147 feet) in height, but the deviations do not disturb the power of sound. Mr. LIND has the candour to say that the acoustic qualities of a room may be influenced in great measure by the materials of which it is constructed, the arrangement of its various parts, the heating and ventilation; but until a more fortunate number is discovered, he pins his faith on 7 as a multiple, and many ancient and modern mystics would approve of his choice.

FRENCH thieves are agile and ingenious, but it could hardly be expected that any of them would be able to carry off about twenty statuettes from the exterior of a cathedral. A deed of that kind may now be entered in the records of the cathedral of Rouen. The figures stood at a height of nearly two hundred feet on the south side, facing the place known as the Calende. It is supposed that five or six men must have co-operated in the robbery, and it seems marvellous that they were undisturbed by police or people. The figures were purchased by one of the inhabitants of Rouen, and will therefore be replaced in their former position, but there is no clue at present to the vendors.

THE value of municipal records appears to increase as time advances, and their preservation is a duty which corporations should be proud to discharge. Exeter possesses charters and deeds some of which have more than local importance, but there is no muniment-room that deserves the name. The estates committee of the City Council lately investigated the subject, and came to the conclusion that a repository of the kind was needed, but it would be time enough to construct one whenever Municipal Buildings are erected. A conclusion of that kind meant an indefinite postponement of the subject. It did not find favour with a majority of the Council, for it was decided to erect a building behind the Guildhall in which the old records could be safely placed.

THE "Year's Art" for 1895 contains portraits of several artists and amateurs, whose names are known from their etchings and drawings in journals. Mr. WHISTLER appears on the frontispiece. In addition to information corresponding with what is to be found in the preceding volumes, there is a list of about three hundred collectors and a few pages about foreign art institutions and exhibitions which will be held during this year. The legal cases are brought up to December. The list of British artists now contains nearly 6,000 names, the majority being exhibitors. The new volume does credit to Mr. CARTER'S editing.

HISTORY OF CLOVIS.—NO. 1.—VOW ON BATTLE-FIELD OF
TOLBIAC.

THE prints we have already published after the wall-paintings in the Panthéon of Paris reveal the peculiar Church and State character of the series. It might be supposed there was anticipation of a coming time when the building would be once more used for religious services, and the paintings were accordingly treated in a manner which would gain tolerance for them from the ecclesiastical authorities. The works relating to CLOVIS, of which we publish the first to-day, have the same sort of dualism. Three of the panels are furious battle-pieces, but angels may be said to take part as guides in them, and the end of the struggle is shown to have been attained in the baptism of the chief, which was followed by the acceptance of Christianity by his followers.

As CLOVIS was a Frank, who conquered a German tribe at Tolbiac, it is assumed at the present time that he was an ideal Frenchman, who merits to be taken as a model for imitation by the youth and manhood of France. It is ignored that he was a German, and that the battle of Tolbiac, where he commanded, instead of being a contest of patriots, with the Gallic cock for a standard, against the enemies of their country, was simply an endeavour of one horde of wild invaders to turn back another horde, in order to limit the numbers among whom the spoils of Gaul were to be divided. The identity of the Franks with the Germans has been accepted by the foremost historians of France. GUIZOT, for example, relates that in the fourth century some members of the tribes in Germany, among others the Franks and Saxons, made a step forward in civilisation and became agriculturists, while the majority adhered to the wandering life. Hence the difference in the accounts of the people. While the German historians speak of the Franks, Saxons and Suevi who remained upon the soil, French writers treat of Franks, Saxons and Suevi who crossed the Rhine. AUGUSTUS THIERRY also, in narrating the events of the second part of the fifth century, relates how the Germanic League, known during two centuries by the name of Franks, or intrepid warriors, descended in several bands from the mouths of the Rhine and Meuse upon the central parts of Gaul. At the same period another tribe seized the country west of the Rhine and became known as Visigoths, while a third, the Burgundians, held the part on the east side.

There were many descendants of Roman colonists in Gaul in the fifth century, but they were unable to resist the northern invaders. The Germans, known as Burgundians, appear to have lost some of their ferocity in their contact with the colonists. But the Franks, according to THIERRY, took pleasure in ruin. They destroyed churches as well as other buildings, and spread so much havoc, there was a probability that all Gaul would submit either to the Visigoths or the Burgundians, in the hope that under either of those invaders there would be a little more chance of survival. Gaul, it should be remembered, was, prior to the invasion, probably the most civilised part of Europe. As Cardinal NEWMAN says:—"That famous country, though in a less favoured climate, was as cultivated and happy as Asia Minor after its three centuries of peace. The banks of the Rhine are said to have been lined with villas and farms; the schools of Marseilles, Autun and Bordeaux vied with those of the East and even with that of Athens; opulence had had its civilising effect upon their manners, and familiarity with the Latin classics upon their native dialect." The clergy were the only organised guardians of civilisation at the time. Many of the colonists were Aryans, and their belief was communicated to the Burgundians. Accordingly there was a large party in Gaul who would not submit to the Roman Church. The Gallo-Roman clergy in the fifth century appear, however, to have exhibited the same sort of spirit which Colonel ESMOND describes as characterising his Jesuit teacher, Father HOLT, after the failure of the scheme to restore the STUARTS. The indomitable priest turned up in America, we are told, very old and busy and hopeful, and as eager to go about in a blanket and war paint to convert the Indians as he had been to exercise diplomacy in courts and camps. When, in Gaul, "the prospect of the smoking ruins could alone distinguish the solitude of nature from the work of man,"

the clergy retained the calmness which can conquer the strongest.

Towards the close of the fifth century, when the disorganisation was at its worst, CLOVIS, or as he should be called, CHLODOWIG, was approaching Gaul. He was the idol of his tribe. His victory over SYAGRIUS in 486 was destructive of Roman dominion in Germany, and made him a hero. CLOVIS seemed, therefore, to be the coming man who was to subdue Gaul and all the German tribes within it. His march would be supposed to mean that the time was favourable for invasion, and accordingly the Alemanni, or Suabians, made a simultaneous attempt. CLOVIS was not the man to labour for the profit of others, and he resolved to test the strength of his competitors. The battle was fought at Tolbiac. In the course of it the Franks appeared to be overcome. CLOVIS was wounded, and as he felt he was helpless, he made a vow that if his enemies were defeated he would adore the god of his wife CHLOTHILDE, who although a Burgundian was a Christian. He gained his desire and respected his promise.

M. BLANC's picture expresses the incident in a marvellous way, although only a few figures could be employed in the compartment. According to some legends CLOVIS was only a youth of fifteen. MONTESQUIEU has a note on the subject, but nobody can say from it whether he credited the tradition. M. BLANC wisely avoids making the chief appear so young. He is seen supported by a couple of youths, for historians believe that what TACITUS says about the Germans of his time was no less applicable in the fifth century, viz.:—"To be surrounded by a band of young men is the source of a chief's power, in peace his highest ornament, in war his strongest bulwark." The Roman historian also explains the action of the women when he says:—"Their wives and mothers accompany them to the field of battle, and when their relatives are wounded count each honourable gash and suck the blood. They are even daring enough to mix with the combatants, taking refreshments to them and reanimating their courage. . . . They have accounts of armies put to the rout who have been brought to the charge by the women and old men preventing their flight." The excitement of men and women is contrasted with the inertness in all but one of the oxen. The angel in the sky suggests the issue of the contest. Every figure in the picture presented difficulties, and the breadth shown in modelling them is undeniable. Whether such vigorous action is the best adapted for mural painting, or how far M. BLANC's work departs from precedent, need not be considered. The French Government laid down no restrictions for the painters, and there was no more thought of making their art subservient to the architecture than when the big battle-pieces were ordered for the gallery at Versailles.

(To be continued.)

PRUDENTIAL ASSURANCE OFFICES, NOTTINGHAM.

THE numerous offices of the Prudential Assurance Association have features which recall the chief office in High Holborn, arising from the use of red brick and terra-cotta in their construction. One of the latest additions is in Nottingham, and the site offering advantages, Mr. WATERHOUSE was able to introduce a low tower, which gives emphasis to the building. The drawing from which the illustration was taken was exhibited at the last exhibition of the Royal Academy.

NO. 40 BERKELEY SQUARE.

ONE of the signs of the times is the alteration which is taking place in some of the dignified but dull streets of Mayfair and other parts of the West of London. Even Harley Street, Wigmore Street, and the neighbouring streets in a few years will present an appearance which will surprise strangers who accepted TENNYSON'S "long unlovely street" as the most characteristic description of them all. The alterations in the West End take many forms, from painting a hall door in vermilion, white, or ultra marine, and introducing a capacious parlour window, to transformation of the whole front. The improvement that is feasible by a moderate outlay will be plain to anyone who compares the house shown in the plate with those adjoining it, which are survivals of that naked and severe but grimy

simplicity which was supposed to be the most suitable characteristic for the town residence of an English gentleman.

ATHOLE HYDROPATHIC PITLOCHRY.

THE extravagant charges of Scottish hotels have had the effect of creating large buildings or hydropathic establishments which are patronised mainly by Scotsmen, who as wise folk are indifferent to the distinction which comes from paying in excess for board and lodging. The establishments have generally the advantage which picturesque and healthy situations can impart, and are besides skilfully arranged. The Pitlochry Hydropathic which we illustrate cost altogether about 80,000*l*. It is one of the best known works of the late ANDREW HEITON, of Perth, an architect who was esteemed throughout Scotland. We intend to publish views of some more of his buildings, and of various classes.

THE architect of the houses in Mount Street, published last week, is Mr. JOHN E. TROLLOPE.

ST. MARY'S, STAFFORD.

THE jubilee of the restoration of St. Mary's, Stafford, was lately celebrated. An address was delivered on the occasion by the Rev. Canon Browne, in the course of which he said:—

The beginning of the religious life of this district takes you back to very early times indeed. There are very many parts of the kingdom which cannot show so early a record as yours. The record has itself been somewhat obscured by the fact that events of later date have been interpolated in later Latin in the old record. But both from the language of the original part of the record and from the correctness of its geographical and other details, I am myself persuaded that it embodies a true tradition. The knowledge of these details had entirely died out in the later Middle Ages, when, if ever, the record was invented as a romance. We know now what they certainly did not know in those times of the connection between this country and Ireland, by way of Chester and of the roads which diverge from Chester, the one leading to London, the other to Leicester, and the details of the story fit in with what we know. The story is that a prince of the Mercian royal house, having gone to Ireland, escaped from Ireland under circumstances which I need not describe, fled to Repton, and there lived the life of a recluse. After a time he came and lived upon an island, where your river divided itself into two and flowed round some considerable piece of ground. This island was called Bethn Ey, where, the record says, is now Stafford.

Before I leave this hermit Bertelin, or more probably Bertelm, for I think that the name Bertelin is probably a mis-writing for Bertelm, and that all the names Bertelin, Bertolin, Bertelm and Bertram are one and the same, I will venture upon a suggestion as to the origin of the name of your town. I do not know what the local antiquarians have ever made to be the meaning of the Stæf in your name. That it is the Anglo-Saxon Stæf is certain from the fact which I shall mention next in order of date. And again it is certain that it was not the name of the river which was crossed here by a ford. Now we are told that when Bertelm was driven from his island he fled to the mountainous districts in the neighbourhood. This would naturally mean that he retired towards Derbyshire, and found himself in what is now the beautiful vale of Ilam, the original of Johnson's Happy Valley. There are half-way up to Ilam, at Checkley and at Ilam itself, very ancient sculptured stones, the shafts of what have been most beautiful crosses. They are quite unique, so far as I know, among the unique monumental treasures of our early past in these islands, treasures such as no other nation as far as we know possesses. At each of these places there is a very singular figure on the shafts, clearly intended to represent the same thing throughout. It is the figure of a man whose body and head are formed of interlacing bands, and who holds in each hand a long staff, reaching to the ground, passing up as high as his head. It is quite clear to anyone acquainted with these monuments that there was in the mind of the designer a definite and consistent intention in these repeated representations. I suggest that there was some event in the history of the person here represented which connected him in some special way with the use of a staff; and as I believe this to have been Bertelm, I think that the ford of the river where he lived on the island was known from this event as the ford of Stæf. This Bertelm was the patron saint of your town, and I

need not tell you under how many different forms his name appears in that connection.

We come next to the great event in your history as a town. In the year 913 Ethelfleda, the noble daughter of our noble King Alfred, the famous Lady of the Mercians, devoted herself to establishing places of strength in this district between the two great roads which I have mentioned. She founded Tamworth, and then, in the later part of the year, before Lammass, she founded the burh at Stæf-forda. That was the beginning of your existence, and those of you who live nineteen years more will have the opportunity, which I am sure Stafford will not lose, of keeping its thousandth anniversary.

It seems to me that this is the most likely time for the beginning of the body of secular canons which was established here. The Anglo-Saxons were fond of that method of carrying on the spiritual work of a considerable district, and to the end of the Anglo-Saxon period this continued to be so, as we see from the fact that Harold refounded on a scale of some magnificence the college of Waltham. At any rate, when we come to Domesday we find you set out perfectly clearly as having here thirteen prebendary canons.

In 1129 we come to a very important event. King Stephen granted to the Bishop of Chester, Lichfield and Coventry—for all these were in one pair of hands at that time—the church of Stafford. The bishop was Roger Clinton, and I wish to say a little about him, as it has occurred to me that his history may afford a solution of a problem which has long puzzled you and a great many more besides; I mean the origin of the very noble and very remarkable font in your church. Roger Clinton died at Antioch in 1148. That means that he went on that most disastrous second crusade when Louis VII. of France led a hundred thousand men to the East, most of whom never returned. In 1147 and 1148 Louis retreated to Antioch with his principal companions, after their earlier defeats by the Turks, and Louis and some of his companions made a pilgrimage thence to Jerusalem. It was in the latter year that your bishop died at Antioch. Now I would suggest that Bishop Roger, who had thought so much of your church of Stafford that he had got a grant of it from the king, had it in his mind when he was dying; and that one of his attendants came home and carried out his wishes by designing and having made this beautiful relic of antiquity, your font. It seems to me that this surmise meets all the complicated difficulties which the font presents. The Byzantine lions are thus accounted for, as well as the singularly Oriental contour of the four great lobes which form the font. The inscription at the base is strictly in keeping with this suggested connection between Stafford and the far East—"Non es discretus si non fugis, ecce leones"—"Behold, thou art not wary if thou fleest not from lions;" it takes us in thought to a country where the lion walks about seeking whom he may devour, and can actually be pointed out to unwary folk. And the very curious inscription on the upper part of the font is in keeping with the suggested connection between Stafford and Antioch and Jerusalem—"Tu de Ierusalem: Ro alem: me faciens talem: tam pulchrum tam specialem." The mention of Jerusalem is, without some explanation of this kind, a great puzzle. With this explanation it is possible that the second of the four portions of the inscription contained the name of the donor, conceivably Roger himself. In that case the font is represented as speaking its gratitude to the donor, who, "from Jerusalem," made it "such as it was, so beautiful, so rare," or possibly "so shapely," but "rare" or "unusual" would in this case be exactly in point. The usual theory is that the person baptized is speaking his gratitude to the font for making him such as he had now become—so fair, &c. The second portion, on this supposition, may have run, as has been suggested, "rorem mihi das genialem" ("givest me the genial dew"), probably in reference to "the dew of Hermon, which fell upon the hill of Zion." It is clear, however, that the font is represented as addressing the beholder in the other inscription, "Non es discretus," &c., and it appears more natural to make the font speak in this case too. On the other hand, it might be suggested that the recently-baptized person addresses the longer inscription to the font, and the font replies with the warning that baptismal grace will not of itself save him from the lions. The latter half of the longer inscription forms a hexameter verse with a double rhyme, and the earlier half forms a very clumsy beginning of a hexameter, which the words "rorem mihi das genialem" would complete. It is, however, certain that the words were not "rorem mihi das genialem," for this would mean fourteen letters and two stops in the broken part, whereas there is only room for ten or eleven letters and stops. "Roger: de: Bartalem" would exactly fit the space. I need scarcely say that if there is anything in this theory the font spent the first fifty years or so of its existence in the earlier church, which stood, as I believe, to the westward of this.

We come now to one of the most interesting coincidences which I have come across—the coincidence of two pieces of evidence which have nothing at all to do with one another. We

learn from Tanner's "Notitia" that King John founded the College of Canons here. This, of course, means that he gave it a more formal constitution, for it had existed, as we have seen, long before this, and it implies, I suppose, that he or somebody else in some way assisted its endowments at that time. And we learn from the record of these beautiful arcades, and the capitals of these noble clusters of columns, that precisely at this time this great church was as a fact begun, at a very early period of the Pointed style. All persons qualified to judge are, I suppose, agreed that the earlier part of the work was done, say, from 1180 or 1190 to 1220; and King John reigned from 1199 to 1216. The record of the stones tells us that the work went on, as indeed so great a work must have gone on in a place which cannot have been very wealthy, for a very considerable number of years. The beautiful choir was probably finished about 1270, and the whole church about 1360.

As I believe, this church of St. Mary was put on a new site, the old church of St. Bertelm being retained for use while the new church was in building, the canons, of course, using the old choir for the collegiate services, and having an altar for the service of the people at the east end of the old nave. But the old church continued to be used as a church for some time after the date which is assigned to the finishing of the present church. This is shown incidentally by an event which caused much excitement here, and led to those interpolations of later date which have cast doubt upon the earliness of the record of St. Bertelm. In 1386, one Willmot, a Stafford man—I do not know if you have Willmots among you still—who had been blind for sixteen years, was restored to sight at the offering of the Eucharist in the Mass by the priest, Joannes Crostys, in the church of St. Bertelin in Stafford.

In 1446 the church and college were granted to Humphrey, Duke of Buckingham, by Henry VI. It does not at first sight seem that a Duke of Buckingham had much to do with Stafford; but, as a matter of fact, this was one of the ancient lines of lords and earls of Stafford. There had been ten in the direct male line from father to son before him, and there were ten more before the male line ended in 1637. He got his Buckingham titles through his mother, a royal princess who transmitted to his grandson and great grandson that claim to the throne which brought them both to the block. It appears from the grant that the Duke of Buckingham had undertaken to give a hundred marks to the collegiate foundation, and I think it not improbable that advantage was taken of this to make the change from the old church to the new as a parish church. The money would amount in these days to quite a thousand pounds. If the people of the parish were to move into the nave and aisles of the new church, with the small lancet windows, which gave the only light, and the very low-walled aisles, the money would not unnaturally be spent on making the aisles loftier, inserting the larger windows in the aisle walls, raising the roof, and constructing the clerestory of the nave. The architecture agrees with this guess quite well. The old church, which adjoined the new at the west end of the south aisle, was thenceforward used as a school. Some time later than this, probably about the year 1500, the latest and poorest alterations were made. That was a time when, as we learn from wills in various parts of the country, a great deal of money was being spent upon church building and church repair. There was a sense of impending change, and the people seemed to wake up and endeavour to put things in order before the threat should come nearer.

The Reformation came. The College of Canons of Stafford was granted to Henry Lord Stafford, who had been deprived of all the titles and claims which came to him from his royal blood. He naturally would have done as other grantees in like cases did. They pulled down or appropriated to secular services the choir of the church with which the college granted to them was connected. The noble choir with its aisles, which are so beautiful a feature of this church of yours, would have shared the fate of scores and hundreds of others. You may see what has happened in the chancel of the church at Arundel, where the monuments of the Duke of Norfolk's ancestors are, or in the void place at the east of the noble Romanesque church of Blyth in Nottinghamshire. But in 1572 the church was regranted by the Crown to the burgesses of Stafford and they preserved it. We owe to the burgesses of towns two of the most striking churches we now possess. The great church of St. Albans, now a cathedral church, was to have been pulled down, but the people of the place bought it and preserved it. The same thing happened with the great Norman church of Tewkesbury, which has imbedded within it the church of earlier, probably Saxon times. Here in Stafford the choir and its aisles were used, as we know, and as some of you perhaps remember, for many purposes not ecclesiastical, and the altar was under the tower, where the people's altar had always been before the Reformation, the altar of the college being of course at the east end, or within one bay of the east end of the choir itself.

Fifty years ago the people of Stafford carried out the great restoration which brought the interior of the church to the

state in which we now find it, and it is that event which we to-day commemorate. The work of restoration has not ceased meanwhile. Much has been done to the exterior which was left undone at that time and needed doing. The noble choir in its full dimensions, broader with its aisles than the nave and its aisles, speaks to us clearly of the existence of the College of Canons here, who used it as their church. It has been enriched within the last few weeks by worthy gifts; the altar and its frontals, the beautiful candlesticks and other furniture of the altar, tell us that the succession of benefactors has not ceased. The canopies over sixteen of the twenty-four stalls are a very beautiful addition to the ornament and dignity of the choir, and they tell us of the advantages of an enclosed choir in the resonance which those who speak and sing, and those who listen, alike observe as the result of their presence.

MODERN STYLE FOUNDED ON ANCIENT GREEK ARCHITECTURE.*

THE various attempts at the revival of some ancient style of architecture being now laid up, one and all on the high and dusty shelf of failure, it may be worth while to discuss the practicability of another revival. Suppose we were to try to revive Greek architecture, how should we go to work?

The revival of a style must be of its essence and not of its mere outside forms alone. If we say that no revival of Greek architecture has been attempted we say so without ignoring the court houses and lyceums of white pine painted white, which were often faithfully studied as to diameters and entasis and the like, from Stuart and Revett, either directly or at one remove. They did not and could not constitute a revival, because they were only a simulacrum in wood of a massive stone original. So is a soap bubble of the form of an old smooth-bore cannon-ball, but yet hardly of its nature.

The Gothic revival has failed because the modern world does not construct and cannot carve stone as the Mediæval men constructed and carved.

The Romanesque revival of which we have heard would hardly have a chance of success among people who are scientific in building when they choose to be so, and who build slightly, cheaply, with thin walls, for a brief season and for profit. How should such a people take up and go on with a style created by childlike and single-minded folk; unscientific workmen building heavily because they did not know enough to do otherwise?

Roman architecture would seem to suit our occasions, for we build and decorate, as the Romans did, at two different efforts; first we build, then we decorate, and that is the Roman language of art as absolutely as Latin is the Roman language of literature. But then, Roman architecture is not a thing that ever lived with a life of its own, and so it appears that nobody has tried to revive it. It was never a subject of evolution, it was created ready made; and so our taste takes bits of it, on occasion, taking them also ready made, but without the enthusiasm of a revival.

But Greek architecture is a different thing. Simple, autochthonous, arising naturally out of the necessary processes of building, it is as human as Romanesque, as direct and logical as Gothic. Unknown to Europe until a century ago, it became the admiration of some builders and architects at a time when the long, slow process of development of style out of style, maintained since the eighth century, had come to an end amid the uproar of the great revolution. It helped a little to purify and also to formalise the work of a few architects, and it gave a fresh life and a new shape to the "colossal order," as it is called, that is, the use of columns more than one storey high in ornamentation of a many-storeyed building; also it covered the United States with pine wood and white painted ghosts of temple porticoes; but it is odd to see how little direct effect the study of Stuart and Revett and Chambers and Cockerell had upon the architectural mind of Europe. We cannot stop now to analyse that indifference; we must begin at the other end, and set up the *à priori* reasons why such indifference was natural.

What could the European architect hope to make out of a style which had no mortar or cement, and set stone upon stone with carefully fitted dry joints? of a style which admitted no arch construction of any sort and no corbels, at least in its maturity, but limited its buildings to post-and-beam construction? of a style which presented no single instance of a window, unless indeed the uncritical people of those pre-archæological days took the windows in the west wall of the Erechtheion for original specimens? of a style which offered no single instance of a chimney, and by which the great Quatremère de Quincy was encouraged to make his famous statement that chimneys were unarchitectural and must be

* A paper by Mr. Russell Sturgis, read at the Twenty-eighth Annual Convention of the American Institute of Architects.

ignored? of a style which offered no instance of the superimposition of storey upon storey, except in the two-storeyed open colonnades of Paestum and, though this they wouldn't have known, of the Attalos portico at Athens? of a style which has left us no vestige of an architectural interior, and which did not provide for interiors in the Roman sense or in our modern sense?

What could they do with such a style as that but what they did, namely, appropriate a few of its details and spoil them in using them?

But for us archæology has done its perfect work, and we know how to discover the spirit of a style of art and to weigh and measure it, imponderable as it may seem, and to inspire ourselves with it, if it should prove weighty and vast. Lord Lytton tells of a not difficult experiment in occult science, to raise from the ashes of a burnt flower a simulacrum of that flower, in form and its colours, as it lived. So, from the scattered bones of temples and boundary walls and porticoes, by dint of careful measurements, minute comparison and much hard thinking, our archæologists are showing us how to raise the perfect eidolon of a Greek structure. Perhaps the colouring of it escapes us as yet, but the form and the build of it are to be made out rather clearly, and in a general sense its sculptured decoration too. So, as we study these living shadows which we evoke, we see and feel how a Greek would have grappled with other problems than those which he had to study. It would not be so very hard to find out how a Greek of Pericles's time would have designed the Eiffel Tower.

In certain ways the architecture of the Greeks is exactly what we need. Most of all, it is tranquil and reposeful beyond other styles; and, if I know the mind of our community, tranquillity and repose in a building are the things it loves best. It is hard to believe that any fancy for picturesqueness and irregularity will ever be more than temporary. Sharp gables do not please so well as level cornices. In city architecture, at least, the level line, the horizontal line is everything except for a tower now and then; and even the tower may be horizontal in its lines, and then the tower is to go out if all our buildings are to have a tower-like altitude.

Therefore we begin with this proposition: we love Greek architecture and find it fitting for our purposes because it is tranquil and serene.

Secondly, it is what we need because it tends to use few and somewhat large parts, and rejects utterly the scale of the human body. That scale of the human body is one of the peculiarities—yes, and one of the virtues—of the Mediæval styles. Greek architecture seems to have ignored it wholly and designed its large and its small porticoes on the same principle exactly, each proportioned within itself. But this has always been the taste of our community. The best-loved buildings are those which have a few large—unreasonably and uselessly large—parts. If a house has 4-feet windows, and you should build a copy of it with 9-feet windows, you would be building a structure sure to be admired. That is absurd; it is ignorance—yes, but the more matured taste of the people and the time also is in that direction.

Thirdly, it is what we need because it does not depend for its effect upon any strongly-marked constructional peculiarities. Greek building has no strongly-marked structural peculiarities: all is post-and-beam or else mere solid piling up, and the design is so far from depending upon even that simple way of building that the Greeks took all the pains in the world to make their buildings seem to be monolithic, covering the courses and the joints alike with a sheet of stucco. Now our modern building, though it includes many processes and many methods, is on the whole devoid of any architectural character resulting from the methods of building.

This brings us to another reason why the architecture of the Greeks is exactly what we need; it is so because what peculiarities of building we have in modern times are mainly of the post-and-beam sort. The Greek could trust his hard marble for 10-feet spans, the load upon them not being great; we can trust our compound iron girders for 40-feet spans, or indefinitely more with light loads, and 18-feet or 20-feet spans with a lofty superimposition, storey above storey of piers set anywhere. The difference in scale and power is enormous; the difference in principle is not very great. Our whole steel framework system is a post-and-beam system and nothing more, and the only essential difference between this and the Greek system is that we secure our posts and beams together, and that strongly at the points of contact, which the Greeks never did or did only with slight aids to accurate adjustment and no more.

Fifthly, it is what we need because the Greeks made little use of architectural sculpture, limiting their decorative carving to slight modifications of the anthemion, of the ivy-leaf scroll, of the alternation of balls and sharp points which we call the egg-and-dart pattern, of frets and meanders. A pattern like that anthemion which we call the honeysuckle pattern once created is dwelt upon, reproduced with a thousand slight and subtle modifications, applied to painting on terra-cotta and in vivid colour on marble as well as carved in low relief; it is a

stock ornament, and a dozen such stock ornaments make up the stock of Greek architectural sculpture. The impulse to carve freely and boldly with deep incisions into stone or with broad flow of leafage in marble never seems to have come to the Greeks. And I need hardly point out how free we moderns are from any such impulse, and how readily we could follow the example of sticking to a few accepted patterns, a common stock-in-trade. We might or we might not be able to invent the few patterns in question; we could certainly adopt them though—"convey, the wise it call"—from the east and the west, and reach a common agreement as to the orthodox borders, friezes, panels and capitals.

Sixthly, it is what we need because the Greeks in their buildings used free sculpture, perfectly realised and wholly scientific, and used it largely, not as architectural sculpture, for it is not that, but as sculpture which the building was to set off. This is so obviously a way of proceeding fit for our purposes that we need only recall such a structure as the new Hôtel de Ville, of Paris, with little carved ornament but adorned by many portrait statues set against the piers of the principal storey, and by other highly finished and complete sculpture. It is to be noted, too, that the Greek sculpture is akin to our own or ours to it, in that absence of the decorative instinct, that basic study of the human form for its own sake, which distinguishes free and pure art from ornamental art. We can secure the services of admirable sculptors, and there is no reason why our buildings should not be, as the Greek buildings were, very severe and plain, very little helped by purely architectural ornament, but settings for much noble figure sculpture.

Finally, Greek architecture is what we need because the great charm of the architecture proper, that is, of the building made beautiful of the Greeks, is a refined and significant finish, a completeness and faultlessness in section of mouldings, in minute proportions, in invisible and unguessed curvature, all coming of thought and care and patient elaboration. These things are not in our way at present. The headlong race for business and for getting through business is not the way to fine designing of any sort. But again, thought and care and patience are in our way in another sense. To devote one's self, body and bones, soul and spirit, to the development of a work of art is the way a sculptor works, if he is of any use as a sculptor. It is not without absorbed attention continued through as many hours or as many mornings as may be necessary that a painting of any value is evolved from nothing. Whenever and wherever a work of architecture may be taken up as a work of art, with something like the sculptor's or the painter's purpose of succeeding and prospect of succeeding as an artist, then and there will be patient thought and a delighted lingering over every detail. The example of the Greeks will then be there to show those who will work in their way how perfection in a few simple things may be reached in a generation, and how adequate are these few and simple things made perfect to make a style great.

Still, before we sit down to the working out of a design for a twenty-storey hotel in the Greek style, it is well to consider what we are to do about the features which the Greeks, so far as we know, never used—about arches where they are needed; about chimneys where they will draw better if carried up high or serve better if put into prominent place; about windows everywhere; about superimposition of storey upon storey; about interiors and their treatment. The "scientific use of the imagination," or rather the use of the imagination informed by science, may indeed tell us all we want to know, and show the designer just how a Greek of the time of Demetrius Poliorcetes would have met these requirements. But perhaps we may as well call in the aid of our predecessors—of those who were nearer to the time of pure Greek art and ask what their methods were. Accordingly we ask the Romans of the Empire how, with a profound admiration for the Greek art but with requirements far other and far wider than the Greek requirements, they found it natural to proceed. We will not follow their example in everything; an inartistic and easily satisfied body of officials as they were with but little of a standard of perfection. But much is to be learned of them; for there was many a big building of the great imperial days which shows little of any influence but that of Greek art in its structure or design, and of those basilicas and imperial forums many instructive vestiges remain. We ask the outlying provinces in the later years of the Empire, and especially those where cut stone in abundance was to be had, rendering inexpedient the use of the familiar rubble-and-mortar and concrete construction. The Count de Vogüé's book and its valuable plates of Syrian buildings of the third, fourth and fifth centuries is our chief guide in this, not only because of the relative abundance of material therein, but because it is evident that Greek feeling prevailed in all these structures, as indeed it prevailed throughout the eastern half of the Empire in fuller strength than to the west of the Adriatic. Besides those smaller buildings of the Hauran and neighbouring districts, there are the stone-built temples of Palmyra, Gerasa and

Baalbec, the vaulted Nymphæum at Nîmes, growing up in the very Grecian atmosphere spreading around Marseilles, and other such stone-built remains in which lies plenty of evidence of the Greek spirit meeting later or Roman Empire requirements. Finally we will ask the Byzantine architects, those wonderful fellows who knew how to take the Roman official stone and mortar building, the Assyrian brick and mortar vaults, the late Italian device of setting rows of arches on rows of columns, and the pendentive vaults (wheresoever they found that), and to combine all in a wonderful style of building with lovely detail. These great men had no sense and no power of figure sculpture. Colour design, especially in mosaic, was their substitute for it, and mosaic is as much in our way as it was in theirs.

All questions may be answered, all difficulties met, all needs supplied in an enthusiastic and inventive following of the Greek style. New capitals, new Orders even, if you must have Orders, would be invented, new ornaments assuredly, and a flexible, adaptable, vigorous style of architecture might come into being, with Grecian Doric, Grecian Ionic and Græco-Roman Corinthian to start from, only of course we must stop measuring profiles and counting diameters and modules; that is not the way to design. We may, however, draw some general conclusions and lay down some general laws nearly as follow. There are reasons for each and every dictum, but they need not be given now and here.

1. The lintel to have preference always in all wall openings, except very wide ones. Arches never to be used unless really needed for constructional purposes.

2. The lintel not to be relieved by corbels but by direct vertical support, as by a column or square pier, near the jamb of the opening, or near the middle of it, as may serve best.

3. Iron and wooden beams to be used freely, for long and short spans alike, and girder construction; double-framed floors and the like to any extent. Girders and beams to be treated architecturally as lintel and as provided above.

4. Ceilings of rooms and corridors to be always flat, never vaulted and never curved or hollowed in any way, except that a camber may be given to beams or girders exactly as the upward curve was given to the stylobate and epistyle of the Parthenon, and for the same reason.

5. Roofs of halls, such as churches, where there is no storey above, to be basilica roofs—that is, of low pitch, with tie-beam construction, the whole, or nearly the whole, truss to show inside, or else a flat ceiling to be hung from the trusses.

6. Windows to be studied from the Greek doors which we possess, and also from the openings between antæ, as in the pronaos of a temple, and also from the tombs at Xanthos and Mylassa, where many short compound piers or free columns carried a very heavy superstructure. That is, windows to be of one of two sorts, either the quadrangular opening framed around with what we call an architrave, simply mitred at the top corners, or else the jambs and the dividing piers alike to be treated with capital and (generally) base, like an antæ. Where the windows are comparatively few and there is much wall surface, the square hole in the wall with bordering architrave. Where the windows are many and near together, the group or succession of openings divided by square piers.

But, as a modification where the solids between the windows may safely be very slight, free columns to be used instead of square piers, but these columns must really be free of the sash and frames. Again, as a possible modification to be worked out with care and caution, an architrave at top and sides of such a horizontal group of windows, which windows would be divided by slender columns, nearly as in some twelfth-century house fronts.

7. In the placing of storey above storey the attempt to be made, carefully and with reserve, to place openings not on a vertical axis, but the openings to be more numerous where they are smaller, and where the storey in the architectural exterior sense is lower. Generally, then, windows fewer and larger, even if subdivided below, and more numerous above. If this cannot be done there is great danger of chess-board regularity, which is good sometimes but not for a whole front.

8. No two or more superimposed windows ever to be treated as one. The horizontal band or motive formed by each storey of windows to be not merely well marked, but to be absolutely supreme.

9. Openings, door or window, to be nearly of the same size for the same building; no huge ones, no great central recessed porches with large opening. This relieves us of all probable need of arches, as in maxim one above.

10. If an arch is ever used it is to spring from a solid impost and to have plenty of solid wall on each side of it. No meeting of two archivols on the top of a column.

11. No arches except semicircular and segmental ones. No flat arches masquerading as lintels.

12. Façades to be avoided. They have come of artificial styles, and are unknown in naturally developed ones. Your design should always turn its corners. In crowded city fronts the edge of the side wall (the gable wall, party wall, or what-

ever it is) to be made the limit of the front. Temple porches, distyle in antis or tetrastyle in antis, to be studied for this.

13. The top of a building to be brought to a double-pitched roof of low pitch, wherever feasible. Such a roof, even above twenty storeys, is manageable. The gable to be cut off square at bottom by its geison invariably.

14. If a horizontal sky-line is wanted on two adjoining sides of a building the experiment to be tried cautiously, of stepping back in three or four degrees to the beginning of the actual roof. If a parapet is wanted, it is back of the geison, on top of these steps, that it should come. Overhanging and beetling effects to be studiously avoided.

15. The overhang of the cornice is, therefore, a very difficult question. On the one hand we have the Greek example of proportioning all parts of a building to each other, no matter how excessive or how limited the size; on the other, we have the impossibility of doing that in the case of high buildings, and also the Greek example of avoiding excess. Probably vertical height will replace overhang, but the design must be throughout.

16. Architectural sculpture is to be of only the simplest character, the Greek honeysuckle and trumpet-flower ornaments and ivy-leaf scroll being taken as the types. Other similar patterns may be added, but with great reserve.

17. The capitals and base of columns in like manner to be of very simple character, the first designs to be based upon the Ionic of the Erechtheion and the simplest and finest Corinthian, perhaps that of the Temple of Olympian Zeus at Athens. New capitals and new Orders based upon them will come naturally.

18. In painted ornament that which is not full descriptive or expressive art to be limited to the simplest borders and patterns, checkers and zigzags and scrolls without leafage.

19. All large expenditure for ornament to take the form of, in sculpture, perfectly realised statuary and reliefs, the best and most sculptural that we can procure; in graphic art, paintings and mosaic on flat wall surfaces, also perfectly free in design—just such as our best painters can give us.

ENGLISH ART SCHOOLS.

AT the annual meeting of the Dudley School of Art, Mr. W. Kenrick, M.P., delivered an address on the present state of the English schools of art. He said he was happy in knowing that there had been great progress made of late years in the character of the work done throughout the country, also in the public estimation in which art teaching was held. This knowledge had forced upon his mind the question, Why were the progress and public appreciation so long delayed? Schools of art had existed in England for more than forty years, but during three-fourths of that time they languished in a precarious state. Their managers had had to complain of public apathy, and the consequent inadequacy of funds for carrying them on, while, on the other hand, those who directed art industries had complained for the most part that they got no good from the schools because they did not turn out ready-made designers who were of any use to them. The origin of "Schools of Design," as they were called in this country, could be traced to the conviction of our national inferiority in artistic design compared with continental peoples, which was brought home to us by the great exhibition of 1851. It was then recognised that the too palpable inferiority of our art wares was mainly due to the absence of artistic training, which placed British designers at a great disadvantage compared with their foreign competitors; and it was believed that if the means of acquiring this training were made accessible to our designers and art workers all would go well with our industrial art products. This, however, proved to be a very partial and incomplete view of the circumstances of the case. It was not only the want of artistic knowledge and capacity in our designers and draughtsmen which needed to be supplied; there was also a want of artistic knowledge and the capacity to gauge and to value good art work on the part of the public, and this acted as an incubus and as a depressing influence, retarding all real advance towards national art. It required a generation, the teaching of Mr. John Ruskin, and the artistic collaborations of Sir E. Burne-Jones and Mr. William Morris, to arouse even a few out of the profound apathy which existed, and to point out the way of regeneration for decorative and industrial art. The revival began, naturally and rightly began, with our architects. The cabinet-maker and upholsterer followed in the wake of the architect—in fact, were often led and directed by him—and the metal-worker, potter and glass-blower brought up the rear of the new artistic army. The result had been that if individuals of even moderate means cared to make their homes pleasant and tasteful at all they could do so now in a way which would have been utterly impossible for them twenty or thirty years ago, and undoubtedly the number of those who cared so to do had greatly multiplied of late years. The

change in public taste and the increased opportunities for gratifying it were brought about outside schools of art, and he thought were little, if at all, affected by the teaching in these schools. This was due to several causes. Finally, the number of students in these schools was comparatively too insignificant to exercise any influence on the outside world; secondly, the teaching in the schools was formal, mechanical and destitute of artistic life and spirit; and thirdly—and this remained to a large extent a stumbling block and an obstacle in the way of the healthy influences which schools of art should have on decorative and industrial art—it was and is fondly believed that art could and can be combined with manufacture in a sort of joint product and glorious British compromise in which the art should not be too artistic, and the manufacture should retain its mechanical, and hence its profitable, character. This was a vain and illusory project, as little possible like the discovery of the philosopher's stone, which should have the property of converting dross into gold. The essence of art work was its expressiveness, its fancy, its variety—qualities which it only retained when the human hand traced the idea in the human brain. No machine had been, or ever could be, contrived as a substitute for the man's thought and feeling directing his cunning fingers. They could multiply a drawing by photography, print in colours from wooden blocks or from steel rollers, and they could have chromo-lithograph imitations of water-colours or oil-pictures, and stencil-painting for wall-decorations, but throughout those multiplying contrivances and processes the truth held good, that the more they were mechanical—as in casting and stamping of metals, for instance—the less they were artistic. Of the three causes to which he had ventured to attribute the failure of schools of art as they were at first established and carried on in these islands, the two former had ceased to operate or operated far less extensively and injuriously than formerly. The third still lingered among us, though he thought he saw signs that it, too, was a vanishing quantity, which ultimately would disappear where interest did not too powerfully sway conviction. Nor did he despair of seeing the day when by common consent the term of "art work" would be exclusively applied to hand-made productions, when people would insist on the real article, however little they might be able to have of it, and would not think themselves any the better off for having spurious imitations by mechanical processes, but, on the contrary, the poorer and the more unhappy. That which had had the greatest effect in popularising and in extending the influence of schools of art had, undoubtedly, in his opinion, been municipalisation. When, as in the case of the Birmingham school—which in this respect at least, as he thought he might say in other respects, led the way in a course which had been largely followed—schools were transferred to corporations and housed in buildings admirably adapted for the purpose, the care and maintenance of these schools became a municipal function, and a higher status in public estimation was obtained as well, and ample financial means were secured. This had led to an enormous increase in the number of students of every class, from the wealthy and cultivated to the poorest children in the elementary schools. It had directed public attention to the importance of the work, and for the first time induced co-operation on the part of the directors of art industries with the efforts of the committees who directed, and of the masters who taught, in art schools. The second cause of the ineffectiveness of schools of art had been removed by a complete revolution in the methods of teaching. The third cause of failure must, he was persuaded, be grappled with by the means they were employing in Birmingham in the branch school specially adapted for jewellers, and also the central school, where they had provided facilities for the designer to familiarise himself with the materials of which his design must be carried out, and by which the art worker might himself learn to design the work which he afterwards executed with his own hands. It was not too much to claim that this would bring about a revival of art work and craftsmanship. The first function of art teaching was purely educational; the second, the more technical one of training the art craftsman, the designer and the artist. Art teaching, for the purpose of drawing out and strengthening the powers of seeing accurately and observing closely in the first place, and of recording impressions in the second place, was applicable to and useful for all young persons, whether they intended to pursue art work as a calling or not. It was also most desirable that the power of judging between good and bad work, and that taste and discernment should be cultivated in all, as well as in those who had the power to produce. Without this general diffusion of artistic knowledge and sensibility we could never hope to create a truly national art. Art workers and artists who had to cater for an artistically blind and dead public would soon become blind and torpid themselves. The artist lived on sympathy and recognition; without these stimulating influences his eye became jaundiced and his hand palsied. The first object of art teaching was knowledge, the power of observing facts; the second was language, the power of expression.

Nothing was more certain than that it was impossible to observe the forms and colours of natural objects and to retain faithful impressions of them in the mind without some power of drawing and painting. To anyone who conscientiously endeavoured to represent what he saw in nature it was little short of a revelation to find how much his senses were quickened, how much his vision was enlarged, how much became apparent and precious to him in the process which had previously been hidden and neglected. After the power of vision came that of expression. The latter power would always, or nearly always, lag far behind the former, and yet the one would advance with the other, so that there would always be a more or less constant relation between them. For this reason an acquaintance with literature, especially the study of the best poets and masters of prose, was almost as important for an artist as for a writer. Refined and delicate art could only proceed from a refined and cultured mind. Such was the inevitable law of our mental and moral constitution. Hence, for the student in an ideal school of art, they must require full access to a good general and art library, a fairly complete museum of industrial art, and a picture gallery containing a few masterpieces of painting must also be provided. With regard to the method of the teaching, he was in entire agreement with what had been quite recently stated by Mr. E. R. Taylor, head master of the Birmingham School of Art, on the subject. After the constant practice of designing and as the most notable aid to art craftsmanship, he (Mr. Kenrick) should place modelling in clay. Of drawing and painting from plant and animal life, and from the draped and nude human figure, he would not speak, as the value of such studies was universally recognised in all good schools of art. Rules and systems which had become formal and stereotyped were worse than useless; they were fetters not aids. There was no finality in the art of teaching. If it was good for anything it would, as Mr. Taylor had hinted, show its vitality by growth. But there was one faculty in the teacher which he held to be essential under any system, and that was the power of sympathy which enabled him to discern latent powers of perception and expression which made up the individuality of the student, and which therefore should be directed, corrected if necessary, but never repressed. Education meant drawing out, and the successful teacher was he who could draw out what was best in each of his students. In the course of some remarks to the students of the Dudley School of Art, Mr. Kenrick said they must be assured it was only that which was stored in their minds from which they could draw when they wished to invent; out of nothing nothing could be expected, and slavish copying of other men's designs was not originality, and it was only by going to the same source of inspiration to which they went—nature—that they could hope to rival them. Constant study, constant and unremitting application—no less the demand upon them—but to such as had the gift and faculty of the artist and art craftsman, what occupation could be more delightful, and what career more satisfying and sustaining?

EXCAVATIONS IN CYPRUS.

THANKS to a generous bequest, says the *Times*, the British Museum has been enabled to start what it is hoped may prove a fruitful series of excavations in Cyprus. The first season's work began in November, 1893, and continued to May, 1894, the site chosen for this preliminary effort being Amathus, the ancient residence of Cinyras, a prince known to Homeric story for his handsome gift of a cuirass to Agamemnon when the Greek fleet was about to sail for Troy. The last appearance of Amathus in history was when King Richard I. of England, on his way to Jerusalem, destroyed it to avenge the ill-treatment which his bride Berengaria had received when some of his ships had been driven for shelter to the harbour of Amathus, then, as Limassol is now, the harbour for the south-west district of the island. The city being reduced and the whole of Cyprus, in fact, made subject to England, the nuptials of Richard and Berengaria took place, she being crowned Queen of England and of Cyprus.

The site had been partially explored by General Cesnola about twenty years ago, but, though fairly successful, he appears to have been disappointed at finding that the tombs where the most valuable objects were to be expected had already been rifled. This, together with the great expense involved in excavating tombs often at a depth of 20 feet below the surface, induced him to retire from the scene.

The Museum authorities decided to see what might remain, or, at all events, thoroughly to explore the site, so that no one need any longer speculate in vain on its possibilities. The experience of Cesnola was confirmed. It was found that the ransacking of tombs during the sixteenth century had been carried out on an extensive scale and with a singular talent for discovering the richest of them, however deep they might lie. Nevertheless, there were many that had escaped, and, though

in some cases the contents were of no great rarity, there was yet no inconsiderable number which yielded objects of first-rate importance in their kind; these have now been arranged for exhibition in the 1st Vase-room of the Museum in case B and cases 30-32.

It was expected from the traditions of Amathus that a class of antiquities might be found which would correspond to those of Mycenæ. But this was not the case. There were, indeed, obtained a certain number of scarabs bearing the cartouche of the famous Egyptian king Thothmes III. As, however, these were found in tombs which cannot by any possibility be older than the sixth century B.C., so conclusive are the other contents, we have thus fresh proof that the presence of such scarabs is of no value in determining the date of a tomb. It had been known before that a factory for the production of these and kindred scarabs existed at Naucratis, in Egypt, in the early part of the sixth century B.C., and as this is the date of the tombs in question at Amathus, we may assume that the new scarabs had been imported from that quarter along with the numerous Egyptian amulets in porcelain which have been a feature of the excavations. Objects of this kind would appeal to the strong Phœnician element in the population with its tendencies towards Egypt. The Greeks were probably not at all numerous just then. And yet it is their artistic remains that attract us most, whether imported from their kinsmen in Greek proper or executed by themselves on the spot. For instance, nothing in the way of enamelling on gold could be finer than the set of spiral ornaments such as rich ladies used in looping up their hair. The process of enamel is the same as in cloisonné, but the delicacy with which minute rosettes have their leaves inlaid in various colours and fused into a harmonious brilliancy has never been surpassed in the remains of art of this kind. Add to this the boldness of design in the gryphons' heads which terminate the spiral. Very interesting also is the small series of engraved gems dating from about the end of the sixth century B.C.—a time when minute and graceful workmanship was the ruling spirit in Greek art. Cyprus was known in antiquity for its collections of gems, and this reputation has been amply confirmed by the number of exceptionally beautiful specimens which it has yielded, first of all to General Cesnola, and since then to the casual explorations of peasants. Among the new gems may be mentioned as singularly refined in conception and execution a banded onyx, on which is engraved in very low intaglio a winged Fate, the stone itself being, as was not unusual among the Greeks, remarkably unattractive. Noticeable also are a war galley extraordinarily minute in its workmanship, a discobolus of a new type, and a cow suckling her calf against a background of papyrus plants on a pale plasma of fine colour. This last is quite excellent. There is a considerable sprinkling of gold finger-rings of various dates. But one of the strangest of the finds was a series of small ingots of gold and of silver made of a uniform shape and apparently of a uniform weight.

Cyprus has long been known for the quality and variety of its glass products, and if the present excavations have not yielded much that is absolutely new in this respect they have, at least, shown that this very beautiful ancient industry had enjoyed much favour in Amathus. Another extensive occupation was the making of statuettes and figures of every description in terra-cotta. Side by side with almost countless specimens of rude local work the usual experience has been to find only occasionally some fine example of the true Greek spirit and skill in the modelling of clay. This has again been the case. In the pottery the result is much the same—a large proportion of rude local ware by the side of a small number of vases imported directly from Greece. Unattractive as the local ware of Cyprus generally is, there are two specimens of some interest in the present series, the one for its grotesque attempt at representing a banquet, the other because, fragmentary as it is, it settles the question whether a certain type of vase with imitations of the Egyptian Hathor head was the product of an early immature art or of a period of decline. These vases are now seen to be comparatively late. Among the terra-cottas we must mention the series of models of ships, which recall the legend of a late Greek writer that Cinyras, desiring to evade his promise to send a fleet to Troy in aid of the Greeks, thought it would be sufficiently true to his word if he sent one warship with clay models of others.

An entirely new feature in Cyprus excavations has been the finding of a series of limestone stelæ or tombstones, on which is painted the figure of the person commemorated. The surface of the limestone is prepared with a white ground, on which the figure is painted in colours and in a manner which strongly recalls the frescoes of Pompeii. They are all of a comparatively late date and have suffered much from having been buried in the earth. The best of them has unfortunately been broken in two and the upper part lost. It has represented a richly-draped woman seated on a chair to the front, very boldly drawn and with a delicate sense of colour. In the course of excavations of this kind it is necessary to have some one present who knows the archaeological importance that may attach to the finding of

one class of objects with another class. During the earlier part of these excavations these duties were undertaken by Mr. Arthur Smith, an official of the British Museum. During the latter part Mr. Myres, of Christ Church, Oxford, voluntarily offered his services. In the next season, which will shortly commence, the Museum will again be represented by one of its archaeological staff, Mr. H. B. Walters.

THE LATE JAMES HAMILTON, A.R.S.A.

THE sudden death from apoplexy is announced of Mr. James Hamilton, A.R.S.A., at the early age of forty-one. The sad event, says the *Scotsman*, took place on Thursday evening, in last week, without premonitory warning, in his own house, 3 Fettes Row, Edinburgh. Born at Kilsyth in 1853, Mr. Hamilton was in his earlier years a house painter, but having artistic tastes he came to Edinburgh and studied in the Life School of the Royal Scottish Academy in 1874 and two subsequent years. He first exhibited pictures in the R.S.A. Exhibition in 1875, and from that date his name has never been absent from the catalogue. Mr. Hamilton's speciality throughout his life was the painting of scenes from Scottish history, especially of dramatic incidents associated with Highland life, and also of interiors touched with homely sentiment and Scottish character. All his sympathies were Scottish. Some years ago he paid a visit to the Continent; but on his return he emphatically declared that there was no place like home, and rarely in his works was he tempted from his allegiance to his native country. An early picture of his which attracted some notice as giving promise of greater things was called "Strolling Dancers of the Middle Ages," which was exhibited in 1881. In the following year he had also a painting of considerable merit, called "James IV. of Scotland and Princess Margaret," in which the young king was represented seated at the feet of his lady love, who played a lute. One of the most successful of his larger pictures about this time was the "Refugees of Glencoe," exhibited in 1884, in the execution of which he took infinite pains, and which was afterwards etched by his fellow Associate Mr. Aikman, and attained considerable popularity. "Leaving the Mountains to Follow Prince Charlie," exhibited in 1889, was also a large picture pervaded with something of the old Jacobite spirit; and he had frequently smaller studies of Highlanders with such titles as "On the Alert" or "A Highland Outpost," invariably conceived in a dramatic vein. In 1893 he exhibited at the Mound a large picture, with subject taken from an incident in the "Legend of Montrose," in which Sir Duncan Campbell, Annet Lyle, and Allan M'Aulay figured. In respect of composition, colour, and character, this was, perhaps, the best of his semi-historical works. Last year he had in the Academy a very happy and characteristic piece of domestic genre, "When the Bairnies are Asleep," the truthfulness of the sentiment of which awoke a responsive feeling in the hearts of the spectators. Mr. Hamilton likewise painted landscape with an appreciative brush. In that, as in his figure subjects, he was sometimes unequal; but one can recall especially a number of Ayrshire coast and land scenes which were of a very pleasing character. He also essayed portraiture, and in this connection his picture of the Rev. Dr. Matheson, of St. Bernard's Church, which was exhibited in 1892, may be particularly mentioned. For some time past Mr. Hamilton was working for a special sale which he was to have had at Dowell's next month. Mr. Hamilton, who was twice married, is survived by a widow and one child. In private life he was, though quiet and unobtrusive in manner, of a social disposition, and had many good qualities, not the least of which were an ardent love of his art and that perseverance which enabled him to surmount many difficulties in the attainment of the position he occupied in his profession.

SIR C. L. EASTLAKE ON THE DECORATION OF HOUSES.

THE painter and scholar who was President of the Royal Academy, Director of the National Gallery, Secretary to the Royal Commission on Fine Art and holder of various other offices, exercised much influence in England. His great abilities were mainly employed to enable his countrymen to appreciate Italian art, and especially the examples of the great masters of the Renaissance. The Blue Books on the decoration of the Houses of Parliament are full of evidence of his knowledge of all the processes of fresco and other varieties of wall-painting when applied to public buildings. The following letter by Sir Charles Eastlake reveals him in a new light, for in it he endeavours to show how far English mansions can be made to correspond with Italian villas of an earlier date, and accordingly it contains suggestions which can never become obsolete:—

The word "decoration," however appropriate to fantastic ornaments, and in some degree to figures, has, as you know,

been considered vilifying when applied to works that are addressed to the mind. But, as we have no other term, we must consent to use it in both meanings. It is, indeed, important to remember that no works of art, however elevated, can dispense with the appeal, the impressive or winning appeal, to the eye. Thus much for our definition of terms.

As a general principle in decoration, I would recommend that the eye should be solely or chiefly addressed where a passing glance only can be given to the work, and that the attention should be more taxed where leisure and surrounding circumstances permit or invite contemplation. The reverse of this would be manifestly wrong; but the recommendation itself is not to be understood too literally. Every display has its legitimate exuberance; the "over and above" in decoration can only be that of quality, for mere taste is supposed to define all that relates to quantity. As common poetic description sometimes exalts its subject less by accumulation than by substituting costly or choice materials for ordinary ones, so in art the augmenting excellence ascends from sense to thought. If, therefore, the intention to afford mental pleasure is very apparent even in situations where this may appear superfluous and in a manner thrown away, the impression must of itself be elevating. But the indispensable condition is that a gradation should still be maintained; that higher excellence should still be in reserve. What must be the character of works of art to which Raphael's corridor in the Vatican forms the mere approach? The answer is given by the perfection of the works in the Stanze. All that is to be insisted on, therefore, is a due gradation in conformity with the principle first proposed. In the remarks that follow, I cannot strictly adhere to the plan of the house, but must often generalise; the observations submitted, if tenable at all, will, however, be easily applicable to your purpose.

The Hall.

The pavement of the halls might be enriched, but I can hardly approve the occasional practice of the ancients in placing "histories" under their feet.* The forms and hues employed should be merely calculated to gratify the sight. Among other preliminary considerations, I would also include the nature of the mere surface as well as the distinction of every apartment. A pavement, for instance, however decorated, should still express the character of firmness and solidity. For this reason I would banish even the lowest kind (that of plants) and every approach to perspective. Geometrical forms would thus be alone admissible; the variety is infinite, but even here I would again exclude abrupt and irregular contrasts of colour, which have sometimes the effect of making the evenness of the surface doubtful; the last consideration is, indeed, applicable to carpets. With respect to the classic fashion of inscriptions on the threshold, I merely remark that letters are only ornamental in architecture when disposed symmetrically within the space which constitutes their framework.

In approving the common practice of placing statues and bas-reliefs in the principal hall, I do not depart from the spirit of our first principles. A statue has generally the advantage of being seen in various points of view, and thus commands attention in situations where paintings could not. Associations of classic taste are naturally connected with the classic materials of marble or bronze; and architecture, when displayed as such, seems to acquire additional solidity by the presence of sculpture. But works of sculpture of the first excellence should be admitted to the library or drawing-room, and even fragments of rare beauty should be enshrined with like distinction. For the present, however, we are in the hall. I do not recommend mixing mural painting and sculpture: no painted devices should compete injudiciously with the bas-reliefs. But let us suppose that your bas-reliefs are in the outer hall, and that you have only some sculptured vases on detached pedestals in the inner hall or corridor, then by all means decorate the walls of the latter with arabesques: to these we shall return.

The Staircase.

In the staircase, also, it will be necessary to make your election between the two arts. I will assume that you decide for painting. Few people linger in a staircase; still fewer break their necks to look at a painted ceiling. If the scene affect the eye and the imagination agreeably, this may be considered sufficient. When we see the whole Pantheon on the ceiling and walls of great staircases, this undoubtedly might be defended on the ground that a mere passing impression of magnificence is intended; but the exuberance of quantity rather than of quality is here obvious. In whatever mode the walls of the staircase are adorned, the decoration should be entirely subservient to the architectural effect. This involves a more radical objection to the mythologic crowds before alluded to, because they have frequently the effect (and intentionally so) of destroy-

ing all idea of the angles of the building. I am of opinion, on the contrary, that the decorator should dispose his paintings in shapes which shall appear to grow out of and complete the architecture. The inclination of the panelling of the wall to agree with the line of the stairs may be considered incompatible with paintings; a horizontal termination, perhaps level with the chief landing-place, is essential, and the triangular spaces or sections of such spaces, between this and the stairs, had better be left nearly plain, and not very light in colour. Of all modes of destroying legitimate illusion, that of introducing painted figures, sometimes the size of life, where living figures must often come in contact with them, is the most effectual.

The compartment or compartments above that horizontal line might be painted in fresco, certainly not in oil on the wall, nor in the newly-revived encaustic, at least not till it has been further tried. The figures should not extend to the angles of the walls where the staircase turns; the pseudo or real compartments which form the frames might finish at a little distance from the angle; the real wall is, in short, never to be lost sight of; and if ocular illusion is attempted at all, it should be rather with a view to complete and enrich the architectural forms than to destroy them. Where the light is unfavourable for painting, the flattest style of bas-relief is still admissible. But as you are especially desirous of having your staircase coloured, I really can propose nothing fitter to gratify the eye and imagination merely, than the more refined but at the same time familiar subjects of the Greek mythology, such as the personifications of poetry, the progress of the hours and of light, the seasons and so forth. Such subjects afford the best materials for mere beauty of line and drapery, for composition generally, and, if not too statue-like, for colour; and even when they suggest no profounder range of thought (not that their import is necessarily thus superficial), they leave an elegant impression on the mind. The objection is that they are old; but there would be some novelty in treating them as detached compositions, instead of beclouding and peopling the whole space in the style of the seventeenth century. It is to be remarked that Raphael and Michel Angelo bounded their compositions of this kind by definite forms, especially on ceilings. Pietro da Cortona and the machinists generally were as intent on destroying the connection between painting and architecture as the great masters were to preserve it.

But this separation of the compositions into compartments supposes at once a great latitude in the choice of subjects. Milton's smaller poems, and many other English sources, might be preferred to classic inventions; only it should be remembered that fresco, from the nature of its means, is privileged to aim at the ideal rather than the actual world, and that the character of the decorations required for the place must necessarily influence the selection and treatment of the subjects. Dark effects are equally unfit for the situation and for the powers of fresco. In the ornamented divisions of the compartments, perhaps partial gilding might be employed with better effect than colours; on the ceiling both might be introduced (in merely decorative forms) unless your staircase ends in light, in which case your glass must of course be ornamented, even if colourless.

The Dining-room.

Dining-rooms, strictly so called and employed, are generally unadorned with pictures, this hardly seems necessary. In theory we may admit that subjects requiring some contemplation would be out of place in a room exclusively devoted to "the table;" but portraits of celebrated individuals and landscapes, although they cannot be duly examined in such moments, may convey associations to which the spectator, even if not particularly conversant in pictures, is supposed to be alive at all times. Portraits of the class alluded to as historic texts are connected with time; as landscape, especially if founded on actual scenes, may suggest the memory of place. A room used for the purpose in question and for nothing else is, however, not the place where fine works of art should be bestowed; and I incline to think that this is the fittest field for small frescoes and arabesques. This, in short, is one of the occasions to please the eye and the imagination merely. Accordingly, in the mode proposed, no definite idea is presented to the mind, but an air of elegant and festive splendour surrounds the guests. There should, however, be endless variety; scarcely a form should be repeated in the details, although an architectural symmetry is, as usual, to be preserved in the masses.

The Morning-room.

A dining-room *per se* is not uncommon, but a professed and exclusive breakfast-room supposes a degree of order in the family migrations, to which the muses could hardly be expected to accommodate themselves. Nevertheless, to complete my catalogue, I will suppose one, or rather I will suppose that one of your drawing-rooms is used chiefly as a morning-room. Indeed, without condemning a family to betake themselves to particular rooms at stated hours, it may be allowable

* The passion for this kind of decoration was carried so far that the ornamented floor of the dining-room sometimes represented the scattered fragments of a repast. Plin. l. xxxvi. c. 25.

to decorate and furnish apartments on such a supposition, by way of insuring a marked and agreeable variety of character. Lucullus had even a series of dining-rooms from the "Apollo" downwards; and we learn from Vitruvius* that the opulent Romans changed the scene of their banquets according to the season of the year. The morning has its own feelings even for those whom affluence frees from any kind of labour. The purposes of the day are unfinished—everything is contingent. Under such circumstances the character or subject of pictures is to be adapted to the mind—not the mind to the subject. The open face of nature by sea and land may here enliven the walls, and agree with the excursive feelings of the hour. The chase and its incidents may here triumph. The English pastoral is here strictly in its place. Solemn themes, solemn effects, should not be admitted, while all that responds to buoyancy of spirit would, on the contrary, be appropriate. It need not be gravely objected that accidental or even average states of feeling may be little in unison with the impressions which the arts profess to give, for the same objection is frequently applicable to all the accompaniments of civilised life, nay, to the beauties of nature, which so often appeal even to cultivated human sympathies in vain. The occasional contradiction is unavoidable, where, of two conditions, one is permanent, the other mutable.

Corridors and Pavilions.

Corridors on the ground-floor, or even upstairs in houses where pictures do not abound, may be fitly decorated with arabesques. The same kind of ornament might be applied to garden pavilions, and, in the present instance, even to your portico next the lake if no statues are there, but not to conservatories, where the conventional forms and tints of art would contend injudiciously with nature. In these decorations it is absolutely necessary to set out with an architectural scheme, and subdivide the spaces with some attention to congruity and subordination. In the details, pleasing masses and forms are essential, because here nothing can be concealed; there is, strictly speaking, no chiaroscuro, no perspective; form and colour are the chief means. The possibility of approaching and even coming in contact with the painted wall, suggests the necessity of a small scale in the objects, and of precision and delicacy of outline; yet, from the circumstance of the forms and hues being relieved on a light ground, they are at the same time effective at a considerable distance.† Stucco ornaments in very low relief, mixed with the painting, are admissible (as they can hardly be said to come under the head of sculpture) but they require a strong light to display them.

I cannot recommend frescoes for the sitting-rooms of dwelling-houses. The sum of enjoyment to be derived from one or two large paintings is not to be compared to that which the contributions of various schools can afford, even assuming the highest merit. Some frescoes of the Villa Madama near Rome, from the school of Raphael, show that such works may be beautifully executed in a small size, but they still seem fitter for open galleries than for rooms. I have only ventured to except the dining-room. The impossibility of change in the apartments we live in is an unpleasant feeling; in a public building, on the contrary, it is satisfactory, and a staircase or a professed dining-room approaches this character.

Family Portraits.

I may here observe that a staircase covered with ancient family portraits is seldom agreeable to the eye; indeed if it were a desirable kind of decoration, centuries must often elapse before the materials would be ready. The first impression on seeing a quantity of portraits in a staircase is that it is an accidental if not a troublesome accumulation, and that there is no room for the pictures in better situations. Far be it from me to speak with any disrespect of the taste for family portraits, so peculiar to the English and so calculated, as Johnson said, to foster their "domestic charities;" but I hold it not always necessary to place the portraits of the household in prominent situations. The interest such works inspire is, in most cases, strictly domestic and private. The portrait has, in short, no pretension to be conspicuous to all eyes till the individual is celebrated or till the work of art is canonised. These conditions, I admit, may often exist from the first moment; but then, *à fortiori*, a staircase is not the place for such a production. The ostentatious Romans appropriated one of the most public rooms of the house (the tablinum) to genealogies, records and inscriptions relating to the family history, and covered the remaining space—often the atrium as well—with the portraits

and busts of their ancestors.* This does not appear to have been the custom with the Athenians.

The Library.

We have decided against frescoes in what are called sitting-rooms; your oil-pictures are, however, to be selected. I shall consider the library as distinct from the drawing-rooms; but it is quite possible to blend their character. The library in the Ducal Palace at Urbino had a room or study adjoining it, decorated with portraits (in this case, by the way, they appear to have been frescoes) of learned men of all ages. In a library, literally to be used as such, pictures of extensive interest seem to be inappropriate. They may be said to divert the attention from the business or amusement of the place. But the portrait of the poet or of the sage is a source of pleasing and elevating associations, and may sometimes command a deep interest. The library may contain the cabinets of gems and medals, the collections of engravings, the terra-cottas, &c.; or if the drawing-room is ample enough, all these treasures of virtu may be deposited there. I prefer a library without coloured decorations; the woodwork may be carved in flat relief, even to the panels of the walls; a mode of decoration now beautifully supplied by embossed leather, which need not be dark in colour. Whatever colour appears, except in the portraits, miniatures or illuminations hung around, should be in the books; these should strike the eye, and be so to speak in the foreground of the picture. Vases or busts may surmount the cases. The ancients preferred the latter; and many, like Asinius Pollio, collected in their libraries the authentic and even imaginary portraits of great men. Among the latter was the bust of Homer.† But the light is generally so unfavourable in the upper part of modern rooms that busts, when placed so high, are reduced to mere ornaments and require the addition of names. This, indeed, is not objectionable in any case, for the interest of a portrait commonly depends on historical associations. I see no objection even to inscribing both the subject and the name of the master under works of art generally: a volume bears its title and author's name, and pictures to many are as sealed books till inquiry is stimulated or interest quickened by similar means. When the description is too long to admit of this, the words "See Catalogue, No. —" might be added.

If colour be admitted anywhere in the library, it might be in subjects on the ceiling, allowable here, if at all, in the region of easy chairs and occasional meditation; perhaps, too, to a certain extent in the windows. The introduction of subjects on ceilings has not been recommended generally, but in the system of arabesque painting the universal decoration of the walls requires to be carried into the ceiling. Sculpture, from the reasons already given, or rather in accordance with the same taste, is quite admissible in the library. Cicero frequently writes to his friend at Athens to send him any good works in sculpture, fit to adorn the library and residence of a man of letters.‡

(To be concluded.)

TESSERÆ.

Cairene Houses.

THE first and all-important object of the Mohammedan architect was to screen the women of the house from the view of strangers. Caïrene building rests on the principle that the inmates of the house must neither be seen of passers by nor see too much themselves of the outside world. Hence the prime condition of Domestic architecture was to build the rooms round an interior court, into which the chief windows looked, and to make as few windows as possible, and those few closely latticed. As a result, those streets of Cairo which are lined with private houses exhibit a somewhat monotonous aspect. The houses are generally two or three storeys high—in the old Mamluk days they were of five storeys—and are built of stone on the ground-floor (coloured in alternate red and white courses with red ochre and limewash), and of brick tied with wood and coated with white plaster on the upper storeys. The doors are often very tastefully ornamented, but there the external decoration generally ends, for the windows on the ground-floor are generally but small rectangular apertures closed with lattice-work, and set high above the reach of curious eyes, and even those on the upper storeys are commonly small and plain, and

* Juv. Sat. 8; Plin. l. xxxv. c. 2.

† Plin. l. xxxv. c. 2.

‡ *Epist. ad Attic.* l. i. c. 3, 8, 9, 10, &c. It is remarkable that a bas-relief, in the finest Greek style, representing a philosopher reading, was found in the ruins of Cicero's Tusculan villa. Some English sculptors and myself during an excursion from Rome, I may almost say, discovered this marble, walled into the staircase of the Episcopal Palace at Grotta Ferrata. A mould was afterwards taken from it, through the exertions of Mr. Gibson, and the cast is now common in Rome. The marble was, I think, afterwards removed to the Vatican.

* *De Architect.* l. vi. c. 7.

† The best examples of decorations of this kind are now accessible to all, in a recent work by Thürmer and Gutensohn, containing the arabesques of the Vatican, the Farnesina, the Villa Lanti, and the Villa Madama, edited by Mr. Ludwig Gruner, and published by Mr. Murray. With this work may be classed the publications of Zahn, on the ornamental inventions of Giulio Romano at Mantua, and on the decorations of Pompeii.

arranged with no regard to symmetry, though there are still some examples of streets where the higher floors of the houses are furnished with richly ornamented lattice-windows. These lattice-windows are called *meshrebriyas*, "drinking-places," from the semicircular or semi-octagonal bow which commonly juts out from their centre, in which the porous water-bottles of the house are placed to cool by evaporation in the air. Unlike the mosques, there are no friezes of ornament or inscriptions on the outer walls of houses. The door generally opens flat against the side wall of the passage inside, turning upon a pivot in the lintel and threshold, and is confronted by the *mastaba* or stone seat (sometimes replaced by a *dikka* or chair of lattice-work) on which the doorkeeper (*bawwab*) sits. Thence a passage, which makes one or two sharp bends, with the intention of foiling any attempt of inquisitive eyes to see into the interior through the door when it happens to be open, leads into a square court, unpaved and open to the sky, in which is a tree shading the well supplied by infiltration from the Nile with somewhat brackish water. No eye should see into the court from any other house, and still less from any street.

The Escorial and Versailles.

Spanish writers have termed the Escorial the eighth wonder of the world. It was erected by Philip II. in the performance of a vow, and was meant to serve the threefold purpose of a palace, a monastery and a mausoleum or tomb. It was dedicated to St. Lawrence and built in the form of the gridiron on which the saint was broiled. According to the computation of Los Santos, accepted as an authority by Prescott, it would take four days to go through all the rooms, the distance to be covered being 120 miles. He states that there are no less than 12,000 doors and windows in the building, that the weight of the keys amounted to 1,250 lbs., and that there were sixty-eight fountains in the halls or courts. The cost was six millions of ducats. The founder of the Escorial was influenced by a religious motive, if a bigoted one. The founder of Versailles thought of nothing but his own personal gratification. He would not hear of completing the Louvre, which Colbert pressed upon him. He wanted something that should date from him and be exclusively associated with his name—something that should stand out in solitary grandeur apart from the capital, which did not afford breathing room for the monarch whose emblem was the sun and his device "L'état: c'est moi." The site was the worst he could have chosen, and its disadvantages, from the nature of the soil and want of water, could only be overcome by enormous sacrifices of men and money. Hundreds of workmen, poisoned by the exhalations, were carried away and replaced at night. Of the 20,000 soldiers and 6,000 cavalry or artillery horses employed very few were found fit for service when they were required for the war. A river, the Eure, was turned to supply the fountains and cascades. Voltaire computes the cost at 500 millions of livres, Mirabeau at 1,200 millions, J. B. Say at 900 millions; M. Henri Martin, making allowance for the altered value of money, sets down the cost of Versailles with its dependencies at 400 millions of francs, or 16 millions sterling. Both M. Baudrillard and M. Henri Martin seem to think that the nation has got value for its money, that Versailles is a monument of which they have reason to feel proud. "History lives in this palace in these gardens; it gives life even to this mythology as a perpetual symbol. After all, is it not France which here shows herself to us brilliant, honoured, powerful?" Considering the year the huge pile was completed, just after the revocation of the Edict of Nantes, we should say that it is rather overtaxed, persecuted, impoverished, depopulated France that is recalled and represented by Versailles.

Picturesque Planning.

In its first analysis architecture is the expression of plan and construction in a building. To speak broadly, there are two faculties displayed in the art—invention and imagination. Invention has to do with the plan and scheme of a building and the relation of its parts; and the artist calls this faculty into play in much the same way as the dramatist creates his characters, disposes of their destinies, thinks out the course of events in his story, and sets the scenes. But in the best work invention goes no further, imagination must do the rest. The eye of the body can go so far, and the rest must be left to the eye of the mind. Having made the plan and settled the scheme of the structure, its height and size, invention retires and imagination takes up the tale. Out of the picturesque plan grows picturesque construction, and if it be a great building like the Parthenon, or Beauvais, or St. Paul's, or York, there is a delicate skeleton of admirably articulated parts underlying and sustaining everything. This skeleton of related parts not only fulfils its primary office of keeping the building from sinking on itself a shapeless heap, but the various constructive features themselves are made beautiful, while they conduce to the general beauty of the whole. It has been wrongly supposed that it is in Gothic art alone that picturesque planning is used as a source of expression. The art of all ages proves to the contrary. To take a typical Classical

example, the architect of the Erechtheum, as Mr. Fergusson has pointed out, took the greatest possible pains to produce variety and contrast in the grouping of the three temples of which the Erechtheum consisted, and no Gothic architect in his wildest moments could have conceived anything more picturesquely irregular than the whole becomes. Indeed, there can be no greater mistake than to suppose that Greek architecture was fettered by any fixed laws of symmetry. Wren's noble series of City churches afford us quite an intellectual treat in this respect, and in order to properly gauge the dexterity of the man, we must bear in mind that the old walls of the churches that had been burnt down were in many cases left standing, to be used as the substructure of his new building. St. Stephen's, Walbrook, is an example in point, where, within the limits of the four plain walls which mark the boundary of the old church, the architect has reared a nave, choir and transept, with a dome over the intersection, and has produced pleasant effects by means of numerous columns, and the domical ceiling which they carry.

The Acropolis of Athens.

The Acropolis in its humiliation must carry our thoughts to the Acropolis in the days of its glory. The mind must strive to realise, however faintly, the splendours of that gorgeous assemblage of structures—to restore in idea, however feebly, these most beautiful creations of human genius. We cannot but form some picture of those superb portals, and that majestic flight of steps by which the Panathenaic pomp ascended to the shrine of the virgin goddess; of the glorious sculptures which almost lived and breathed on pediment and frieze and metope; of the long lines of sculptured forms which graced every avenue, while far above all the brazen statue of Athena kept watch over her beloved city. Something also we must realise of the accessories of this marvellous scene—the brilliancy of sky and sun, the lustrous purity of the marble, the tints of gold and crimson and azure which imparted depth of light and shade to the mouldings and sculptures of its magnificent temples. And with the pictures of these exquisite structures must be associated the men who planned and reared them; and an array of questions comes crowding upon us, some of which we may perhaps seek in vain to answer. What is it which invests the works of these men with their mysterious and touching beauty? Whence came the grace and loveliness which they imparted to all on which they laid their hands? Were the forms and the spirit of their art their own, or had both come to them from some other land? What were the laws which influenced their works even to their pettiest details, and infused boundless vigour and freedom into the arts, the literature and the social life of Greece? These are questions which no superficial or hasty thought can ever solve; they are the promptings of no artificial curiosity, no mere antiquarian or archaeological problems. The answer to them will not merely lay open a most important phase in the history of the human mind, but involves results directly practical. The city which Pericles proclaimed as the school of Greece has become also the school of the world, and its influence is still seen in every form of our art and architecture. To trace this influence and assign its cause, to analyse the principles of that art which attained to a degree of beauty never perhaps equalled, certainly never surpassed, are questions of no slight moment and difficulty, and the more so because indubitably the aim of that art was pre-eminently simple and definite. Emotions of grandeur and sublimity, still more of solemnity and awe, may be awakened in a higher degree by the works of other times and countries. The Athenian cared not to oppress the spectator with the cumbrous grandeur of Thebes or Babylon; he sought not to delight and awe him with the soaring height and intricate magnificence of the Gothic minster, or impress him with the sense of indomitable strength and power manifest in the genuine works of ancient Rome; and yet, with a scale just sufficing to save it from meanness, Attic art revealed to the world an exquisite grace and dignified beauty as little marred by defect or blemish as can be any works of merely human hands. Unrivalled in elegance and purity of form it disdained no aids of metals or of colours, which some might look upon as adventitious and unworthy. It raised its statues in stone or marble, in gold and ivory, or in bronze. It decked its superb pediments and architraves in sombre or in brilliant hues; and the colours which modern use would reserve for internal decoration gleamed on the eye of the spectator beneath the lustrous atmosphere of Attica.

Armorial Bearings.

There is no doubt that emblems somewhat similar to armorial bearings have been immemorially used both in war and peace. The shields of ancient warriors, and devices upon coins or seals bear no distant resemblance to modern blazonry. But the general introduction of such bearings, as hereditary distinctions, has been sometimes attributed to tournaments, wherein the champions were distinguished by fanciful devices; sometimes to the crusades, where a multitude of all nations and

languages stood in need of some visible token to denote the banners of their respective chiefs. In fact, the peculiar symbols of heraldry point to both these sources, and have been borrowed in part from each. Hereditary arms were perhaps scarcely used by private families before the beginning of the thirteenth century. We have not any decisive evidence that hereditary arms were borne in the twelfth century, except by a very few royal or almost royal families. Those of Geoffrey the Fair, Count of Anjou, who died in 1150, are extant on his shield: azure, four lions rampant or. If arms had been considered as hereditary at that time, this should be the bearing of England, which, as we all know, differs considerably. Louis VII. sprinkled his seal and coin with fleurs-de-lys, a very ancient device, or rather ornament, and the same as what are sometimes called bees. The golden ornaments found in the tomb of Childeric I. at Tournai, which may be seen in the library of Paris, may pass either as fleurs-de-lys or bees. Charles V. reduced the number to three, and thus fixed the arms of France. The Counts of Toulouse used their cross in the twelfth age; but no other arms, Vaissette tells us, can be traced in Languedoc so far back. Armorial bearings were in use among the Saracens during the later crusades, as appears by a passage in Joinville, and Du Cange's note upon it. Perhaps, however, they may have been adopted in imitation of the Franks, like the ceremonies of knighthood. Villaret ingeniously conjectures that the separation of different branches of the same family by their settlements in Palestine led to the use of hereditary arms, in order to preserve the connection. M. Sismondi seemed to entertain no doubt that the noble families of Pisa had their armorial distinctions in the beginning of the twelfth century. It is at least probable that heraldic devices were as ancient in Italy as in any part of Europe. And the authors of "*Nouveau Traité de Diplomatie*" incline to refer hereditary arms even in France to the beginning of the twelfth century, though without producing any evidence for this. From the thirteenth century, however, they became very general, and have contributed to elucidate that branch of history, whatever value we may assign to it, which regards the descent of illustrious families.

Beauty in Architecture.

Can it be supposed by any who have thought on the subject that beauty of form or gracefulness of proportion, even in mouldings, depends upon chance? Some law, known or unknown, rules each. But is there anything more difficult to define than beauty? We know that there is a beauty in form, in colour, in expression; still, who shall lay down a law of beauty which shall embrace under one head the most exquisite productions of the Classic and Eastern and Western art, and those of the Mediæval periods? Who can reconcile under one common canon the massive column of the Doric and the slender shafts of the Gothic periods? Each has its beauty, and that not a beauty of caprice or fashion. No doubt, then, that there are different qualities of beauty, but still there must be some leading principle, of which these are but various developments. What is the value of M. Fezuz's axiom that "beauty in the arts is but a national or educational prejudice and inconsistent, since it depends only upon the fashion of the time?" Even Sir J. Reynolds contended that beauty was conventional. "One man," says he, "prefers a swan, another a dove." True, but who prefers a goose to a swan?

Pershore and Salisbury.

In 1288 a great fire occurred, which destroyed the tower and nearly the whole church of Pershore. It is probable that the new choir escaped with little injury, as no discolouration by fire is here visible, as is the case elsewhere, though it is possible that the ruined state of the bases of the columns may in some degree have arisen from it. Elsewhere, however, the traces of fire are everywhere to be seen. There is no clue to the date of the work consequent upon the disaster; but its style indicates an interval of about half a century, and Mr. Wickenden tells us that at forty years after the fire the tower and nave are still spoken of as ruinous. This carries us on to nearly 1330. Soon after this the work of reconstruction must have commenced. It would have been most interesting to have ascertained the actual date and circumstances of this work, not only as being a remarkably noble specimen of the architecture of the fourteenth century, but on account of its containing the most remarkable internal evidence of a connection of some kind with the greatest parallel work of the age—the central tower of the cathedral of Salisbury. It may seem strange at first sight to claim so close a parallelism between so gorgeous a work as that last-named and one comparatively so simple as that of Pershore, yet the more carefully they are compared the more convincing is the evidence that they were either designed by the same hand, or that one was directly imitated from the other. The late Sir Gilbert Scott believed that the former was the case, and that the tower of Pershore was a slightly later work of the Salisbury architect. At Salisbury the cathedral had in the main been completed by

about the middle of the thirteenth century, or a little later. The central tower, however, had only been carried a little above the ridges of the four abutting roofs, and the storey against which these roofs impinged was a lantern storey, the walls of which were rendered hollow by a passage through their thickness, fronted towards the interior with elegant pillars and forming window-like screen work. The angles expanded into projecting turrets of a peculiar form, neither square nor octagonal, but a union of the two. These were perforated by staircases. Thus far at Salisbury the work belonged to the thirteenth century; and on this, as a sub-structure, the architect of the fourteenth century created with singular temerity but with great artistic skill the present stupendous tower and spire. Now if we credit the Pershore tower to the same architect, what do we find was the course he followed? Having no lantern storey provided for him as at Salisbury, he commenced by translating that which he had found ready to his hand into the style of his own period. Having erected his lantern storey he proceeded to cap it externally with a battlemented cornice, which is simply a reproduction with trifling alterations of that with which he had crowned the older lantern at Salisbury. Upon this he erected a bell-storey, which is nothing more or less than the first stage of his Salisbury tower, studiously divested of its richer detail. Every feature is alike, though simplified, and the lower stage is merely a plainer version of the corresponding stage at Salisbury, the great distinction being that it is but one, whereas there are two in the prototype, and a spire in addition. The details bear considerable resemblance—the distribution of windows, blanks and piers is absolutely identical, and so is even the peculiar plan of the stair turrets, as also are the very remarkable bands of quatre-foils, &c. which divide the stages of the buttresses. While speaking, however, of the details as being simplified from those at Salisbury, we must except the internal features of the lantern. These of course differ in style as they do in date from the original, but they are far richer and more beautiful; indeed it would be difficult to find a lantern storey so beautiful as that at Pershore, and it stands quite alone in its design. The analogy between Pershore and Salisbury, however, extends beyond the tower. The vaulting of the choir was at the same time completed and the flying buttresses with the pinnacles consequently carried out, and these latter closely resemble those executed simultaneously with the tower at Salisbury; even the little frill of leaves round the bases of the pinnacles are identical, as are also the very peculiar horizontal cuts in the copings of the flying buttresses. Such a multitude of coincidences could not possibly be accidental, nor could they be the result of mere imitation; they seem to be only capable of being accounted for by the two structures having been designed by the same hand, and unhappily they agree in another particular—the utter absence of information as to their date and erection.

Planes in Moresque Stucco.

A favourite habit of the Moors of Granada and Seville in the technical working of their stucco, by the use of which they give an appearance of extraordinary elaboration to their decorations, consists in working different patterns on different planes of the same piece of stucco work. At a distance the dominant lines of the pattern only are apparent; on a nearer approach the pattern comes into sight, which fills up the bold openings left between the dominant lines of the top pattern; and on a still closer inspection, a third series of forms running counter to the main lines on the pattern on the second plane and filling up the interstices of it, may be traced. From their peculiar sharpness it is probable that few or none of the repeats of these patterns were done from moulds by the operation of casting, but that wire or cut-metal stencils were used as guides for the pointed tools and knives, by which superfluous plaster was removed whilst the whole was yet in a plastic state. This method of shaping semi-plastic stucco with sharp tools is likely to have been derived by the Moors from Roman traditions, as many examples of a similar mode of working are to be seen at Rome, Pompeii, Naples, and elsewhere in Italy.

Magnitude in Architecture.

The works of the architect are usually on a far larger scale than those of the painter and sculptor, and therefore subordinate parts may not unfrequently derive even undue importance from their size and unavoidable conspicuousness. In architecture the quality of grandeur is more dependent on actual magnitude than is the case in the sister arts. The architect may even be able to win applause by the forcible effect obtained from the mere bulk and extent. Yet still architecture has this in common with the sister arts, that whatever praise a building may obtain by reason of its meritorious proportions, or of the grandeur of its general effect, those merits are so greatly increased, and the pleasure derived by the critical eye is so materially enhanced by the discovery of those smaller beauties of design that are revealed only by a

close and critical examination of the subordinate parts, that we can never venture to be indifferent to the value of such details. Such has been the opinion of most men of great artistic genius at all periods.

Contingencies in Building.

There is a vast distance between the theorist and the man of experience. The one proceeds on the assumption that all the facts are of a definite class, and limited by certain circumstances; that the materials at hand are homogeneous throughout, and of the best quality; that the workmanship is of the most perfect description; that the season of performing the work is the most favourable; and that no contingency arises which may not be anticipated. But too frequently the most irksome incidents may baffle the practical man at every step. The ignorance or inattention or absence of the assistant or superintendent may afford opportunity for the introduction of bad materials. The inefficiency, neglect, or dishonesty of the artisan may render the work unsound, an unskilful foreman may render it insecure. The dishonesty of the quarryman may introduce a bad material, which the mason may not care to observe. A quantity of dead lime or cement may deprive the mortar of its cementitious quality. A shower of rain, a storm, or a frost, unforeseen, ill provided against, may produce serious evils. A sudden spring, an unknown cavity in the foundations, may cause a settlement. Such are some of the adverse incidents that may arise, and demand all the science, experience, the patient endurance and energy of the well-grounded architect to triumph over them all.

Early Greek Sculpture.

The Temple of Athena, though the most important of the shrines of the Acropolis in the sixth century, certainly did not stand alone. For we have recovered the whole or part of five or six other pediments of small size, and executed in rough local stone. These compositions now form one of the most conspicuous features of the Acropolis Museum and arouse the wonder, far more than the admiration, of visitors. To those who are accustomed to consider Greek art as a thing dropped from the skies, calm, colourless and faultless, they must come with a shock, for both in form and in colour these interesting memorials of the early art of Greece are bold, awkward and wanting in all refinement. Perhaps the most curious of them is the pediment put together by the skill of Dr. Brückner, in which Zeus and Heracles in the midst are fighting back to back against two monsters advancing against them from the corners, on one side the giant snake Echidna, on the other Typhon, a winged figure with three human bodies and interwoven snakes for feet, a monster coloured throughout with brightest red and blue and green, which might seem better suited for the adornment of a Mexican than of a Greek temple to those who have not realised that Greek art, like every other art, was of gradual growth and started from barbarous beginnings. Interesting as these pediments are historically, one cannot wonder that the contemporaries of Themistocles were very ready to thrust them out of sight. But these sculptures are of older date than those of Pisistratus.

GENERAL.

Mr. G. H. Godsall, of Hereford, has obtained first place in the competition for the St. James's School.

The Architectural Subject assigned to the competitors for the prize which is a memorial of Achille Leclère, is a pavilion for the display of Sèvres pottery at the International Exhibition of 1900.

An Anonymous Donor, a lady, has given a sum of 1,500*l.* towards the erection of new Sunday schools at Basingstoke.

The Great Bentley School Board have appointed Mr. J. W. Start, F.S.I., of Colchester and Harwich, as their architect for the new schools to accommodate 250 children, with the necessary offices, playgrounds, &c., about to be erected near the railway station.

The Society of Architects is proceeding with its arrangements for the examination of candidates for membership. The following gentlemen have been appointed members of the examination committee:—Mr. E. J. Hamilton (president), Mr. Ernest Day, F.R.I.B.A., and Mr. George Highton, F.R.I.B.A. (vice-presidents), *ex-officio* members; and Messrs. Edgar Farman, Henry Lovegrove, A.R.I.B.A., Major F. S. Leslie, R.E., Ellis Marsland, G. A. T. Middleton, A.R.I.B.A., and H. G. Quartermain. It is hoped that the committee will be able to recommend several courses of instruction, which have final examinations now held at various educational centres, as

suitable alternatives to one or more branches of the Society's examination.

The Archbishop of Canterbury has accepted an invitation from the Dean of Bristol (Dr. Pigou) to preach the sermon at a special service at the cathedral on May 6 next, in connection with the Cathedral Completion Movement, the work of restoration having now reached an advanced stage.

Earl Cowper, chairman of the Herts County Council, has offered to provide a farm of nearly 300 acres, with a residence and buildings, rent free, for affording practical instruction in agriculture, conditionally on the County Council stocking the farm and working it. He has also offered to erect a laboratory and dormitories.

The Annual Meeting of the subscribers to the Aberdeen Art Gallery has just been held, Lord Provost Stewart presiding. The report showed that the balance against the account was 8*l.* 10*s.* worse than at the same period last year, standing at 108*l.* 5*s.* 8*d.* The Lord Provost said the present exhibition had been the most successful in the history of the institution. The number of visitors was 29,764.

Paisley Art Institute Exhibition has been opened. The Provost mentioned that within the next few days a new Board would be created in Paisley, which could not fail to give a considerable impetus to art education in regard of the management of the proposed new Technical College.

The Manchester Board of Guardians have passed a resolution expressive of their sympathy with the family of the late Mr. James Murgatroyd, who during more than forty years directed the building operations of the Board, including the erection of the workhouse and infirmary at Crumpsall.

The War Office will, it is understood, apply to Parliament for a vote of three millions for the erection of barracks, as the sum of five millions lately granted is insufficient.

Mr. C. B. Fowler, having ceased to work conjointly with Mr. F. R. Kempson, will carry on the business of an architect and surveyor at Old Bank Chambers, Cardiff.

The Bishop of Liverpool on Tuesday, in the course of a sermon, explained why there was no cathedral in Liverpool. He said the cost would be half a million, besides 100,000*l.* for endowment. There was no doubt plenty of money in Liverpool, but he despaired of raising half a million for a cathedral, as it must be remembered that all the people of Liverpool were not members of the Church of England.

The Parish Church, Perth, which forms the central portion of the old historic edifice, St. John's Cathedral, was injured by a fire on Monday that arose from the overheating of a stove. The pews and other woodwork on the ground floor and the west wing were destroyed, the damage being estimated at over 1,000*l.*

The Institution of Civil Engineers has attained its seventy-seventh anniversary. It now numbers 1,846 members, 3,647 associate members, 359 associates, 17 honorary members and 791 students, making a total of 6,660 of all classes.

The New Sun Insurance Office in Glasgow, designed by Mr. W. Leiper, A.R.S.A., is completed. The style is Renaissance.

Mr. Edward de Martino has been appointed Marine Painter-in-Ordinary to the Queen, in succession to the late Sir O. W. Brierly.

The late Sir C. T. Newton has bequeathed his archaeological drawings, diagrams and photographs to the University of Oxford for the use of the Professor of Classical Archaeology.

A Volume entitled "Les Architectes élèves de l'Ecole Nationale des Beaux-Arts" has been compiled by MM. Penanrun, Roux and Delaire, which is a record of the architects taught in the school and their works. The preface is by M. Charles Garnier.

The Memorial-stone has been laid of a new church for Everton, which is to be built from the designs of Mr. George Bradbury by Messrs. J. & G. Chappell, builders, of Walton.

The Church of the parish of Inch, near Stranraer, has been destroyed by fire. The building, which was erected some thirty-three years back, was only partially insured.

An Industrial Exhibition has been opened at Cambuslang under the auspices of the directors of the public institute.

The Umpire, Mr. Christopher Oakley, appointed by the Board of Trade in the arbitration proceedings between Lord Lonsdale and the Manchester Corporation, in regard to the claim by his lordship for 8,500*l.* in respect to wayleave and the value of minerals taken by the Corporation in the construction of the Thirlmere aqueduct, has given his award, allowing 1,664*l.* for wayleave and 327*l.* for minerals taken and used, making a total of 1,991*l.*, 9*s.* less than was offered on behalf of the Corporation with a view to an amicable settlement being arrived at. It will be remembered that the Corporation settled the claims of the other proprietors, and in addition to offering Lord Lonsdale 2,000*l.* they offered to pay all the claimant's expenses.

THE WEEK.

THE most interesting part of the Winter Exhibition at the Royal Academy for many visitors will be the Water-Colour Room, which is occupied with "a collection illustrating the sculptor-goldsmith's art, chiefly of the fifteenth and sixteenth centuries." The room also contains seventeen copies of RAPHAEL'S great paintings in the Vatican, which, although on a much smaller scale than the originals, suggest their grace and nobility. The designs for goldsmith's work range from the early part of the sixteenth century to the close of the eighteenth, and they are attributed to such artists as CELLINI, DÜRER, MICHEL ANGELO, GIULIO ROMANO, STOTHARD and FLAXMAN. They may be said to have a common character, as the majority are deftly drawn with a pen in bistre or sepia, with slight washes of colour. It is evident that a slavish reproduction was not expected; the craftsman was allowed much liberty. There is also a design by GRINLING GIBBONS for the Holder Monument in St. Paul's, as well as the contract deed for the work, the price being 20*l*. Sir J. C. ROBINSON is the fortunate owner of a large number of the objects in the cases. The most interesting are the antique gems, which have the delicacy that is expected in such work. There is, however, hardly one example in gold, silver, bronze, ivory or enamel, in wood or stone, which is not delightful. Many of them exhibit far more of the artistic spirit than is found in paintings, and they will serve, we hope, as a corrective of the modern notion which identifies painting with art, a fallacy that has wrought much evil in this country.

It is, we suppose, only natural that in cases of compulsory purchase of property for public works owners should endeavour to obtain exorbitant prices. The usual rule of trade is reversed, for the buyer and not the vendor is the master of the situation. There is, therefore, probably some excuse for the majority of the six hundred people who have endeavoured to make the Manchester Corporation pay liberally for the ground that was needed in connection with the new waterworks. To claim 100,000*l*. for a property that brings in 500*l*. a year, or two hundred years purchase, does however appear unbusinesslike, although we may allow the standard of value is marvellously elastic. Lord LONSDALE claimed about 12,000*l*., and the umpire in the recent arbitration awarded 1,991*l*., or about a sixth. Proprietors cannot be expected to be impartial, for their self-esteem enhances all things belonging to them. But it is different with experts. The valuers on Lord LONSDALE'S side considered that the property was worth from 12,304*l*. to 12,894*l*. None of the valuers for the Manchester Corporation would go beyond 1,300*l*. Whether his lordship received the larger or the smaller sum is of no consequence to the public. But valuing is a profession and is supposed to be guided by some sort of precision. What can the public believe when they find that one valuer swears that property is worth ten times the sum which a brother valuer fixes for it, or the reverse? They would be amazed if warehouse porters differed to a similar extent in measuring cotton goods, and they must be sceptical about the value of a process which cannot result in a closer approximation than one is to ten.

THE Emperor of GERMANY recently founded a prize of 1,000 marks, which is to be distributed annually. It is offered in the hope that it will promote the study of the examples of Classic sculpture which are found in the Berlin Museum. The subject selected for last year has some novelty. One of the examples is the head of a young woman which was found at Pergamos. The face has the opulent character of the *Venus of Melos*, but unfortunately it is imperfect. The hair was twisted into a knot, but a part has vanished. Still more to be deplored is the absence of the nose. In March it was proposed to offer the prize to the young artist who would produce the best restoration of the head. As a classic nose is straight, it is supposed to be easier to draw or model than an English one that is "top-tilted like a flower." No less than one hundred and

fifty artists believed they were competent to make the required reparations. But when the models were sent in a week ago, it was found that after some months of trial no more than thirty attempts had been followed out to the end. It has to be decided whether any of the models deserves a reward of 50*l*., but the competition will have its use if all who took part in it will henceforth realise the inimitableness of Greek sculpture, and if they will be lenient in criticising the efforts of the Renaissance artists who added legs and arms to old figures.

THE highest honours do not always bring commissions to French artists. When M. TURCAN, the sculptor, obtained the médaille d'honneur of the Salon in 1888 for his group, *The Blind and the Paralytic*, which is now in the Luxembourg, he was justified in believing that his fortune was secure. But since then he has lived in extreme poverty. He bore his misery with stoicism. A few weeks ago he was attacked with ataxy, and his condition could not be concealed. With their usual generosity the artists of Paris promptly got up a lottery for M. TURCAN'S benefit, and several important works were contributed. A sum of about 1,000*l*. was raised. The unfortunate sculptor was not able to make much use of the relief which came to him, for he died on Thursday in last week. M. TURCAN was in his forty-eighth year.

THE rules of a trade society may be binding on members, but outsiders cannot take advantage of them. A decision to that effect has been given in Dublin. Two plasterers in the employment of Messrs. PEMBERTON, builders, were sent to work in Carlow, where they remained a fortnight. It takes only a few hours to reach that town from Dublin, but the men were paid their wages for the day, tram fare and car hire. Their work was completed, and they left Carlow at 10 o'clock on a Saturday. The men received travelling expenses, but Messrs. PEMBERTON considered that by the rules of the society they were not bound to pay for the time spent in travelling back to Dublin. They admitted at the hearing they were willing to abide by the magistrates' decision. Evidence was produced about the interpretation usually given to the rules by the workmen, and after a long investigation it was decided that the men should be paid for the time they were travelling, and they were allowed costs.

USERS of traction engines are likely to find scant mercy from the new parish councils. A more microscopic examination of the condition of roads will follow, and for every rut which exceeds the average depth somebody will be mulcted if possible. The traction engine is considered an arch offender, and a farmer or a contractor who uses one of them must expect to pay more than the sum charged for hiring. It happens also that a great many lawyers have accepted seats on the councils, and they are not likely to allow local interests to suffer if the law affords any remedy. We find, for example, Sir WALTER PHILLIMORE, who is chairman of the Shiplake Council, forsaking black-letter statutes in order to survey the roads in his district, and to explain to his neighbours how the damage arising from extraordinary traffic could be summarily recovered. The law is to be put in force immediately against owners and users of traction engines in Shiplake, as an experiment. It would be wiser to inquire how much it would cost to maintain roads in a condition to sustain such traffic. Engines are a necessity, and every obstacle to their use is a danger to agriculture and trade. If they injure roads it is generally owing to the defective condition of the surface.

WE learn that the Theatre Royal, Cambridge, which has been so ably conducted by Mr. W. B. REDFERN, J.P., D.L. Cambridge, for the last thirteen years, is about to be pulled down shortly to make way for an entirely new theatre, the designing of which has been entrusted to Mr. ERNEST RÜNTZ, architect, who so recently has reconstructed the new Pavilion Theatre, Mile End. The property will be taken over by a limited company, and a large amount of the capital is already arranged for.

OLD LONDON BRIDGE.*

THE construction of a bridge of an unusual character like the Tower Bridge or the Forth Bridge excites in our time little interest except among experts. People have become so familiar with engineering marvels, they accept an addition to the number without surprise. It is therefore possible that the "other Bridges over the Thames built by the Corporation of London," which are described in Mr. WELCH'S volume, may be looked upon superciliously, as if they were insignificant affairs which any student in a technical school could easily surpass. The progress of bridge construction is unquestionable, but it is well to remember how much has depended on improvements in the manufacture of iron. The difference between Old London Bridge and modern bridges of masonry is not so remarkable as to justify the people of the nineteenth century in their assumption of superiority.

Take the latest example of the class across the Thames, the Putney Bridge, as a proof. The roadway is wider than in the ancient bridge, but we must take into account the difference of traffic in Mediæval and in modern days. The waterways were undoubtedly narrower in Old London Bridge. That was partly owing to the system of hydraulics which was accepted, but mainly to the omnipotence of the Pointed arch. If plate beams were still held to be the only safe form of employing wrought-iron (as was the case fifty years ago), the Forth Bridge would not exist. The Mediæval builders were as confident about the virtues of the Pointed arch as STEPHENSON and his followers were about plate beams, and the use of a semicircular form was moreover prohibited, for it would be accounted a sort of heresy. As the gradients of Old London Bridge were an obstacle to high arches, the builders were limited in their spans. We must remember also that the builders of the bridge were compelled to use stones which were comparatively small. In those days there were no enormous blocks of granite available for the masons. It was therefore considered necessary to oppose a large solid mass to the currents, and the durability of the bridge proved that the builders' conclusions were correct. Conservation has altered the character of the Thames. As late as the middle of the seventeenth century the roar of the waters at London Bridge was startling. DRYDEN, in the beginning of his noble essay on "Dramatic Poesy" (a conversation worthy of PLATO), relates how he and some grantees resolved to pass down the river, in order to ascertain the result of the great naval battle which was to decide whether England or Holland was to have "the command of the greater part of the globe, the commerce of nations and the riches of the universe." When they approached London Bridge the sound of the cannon was rendered inaudible, and therefore the companions "made haste to shoot the bridge and left behind them that great fall of waters which hindered them from hearing what they desired." There is other evidence to the same effect, and although some of the noise probably arose from the rushing of water through hydraulic machinery on the Middlesex side, there is no doubt the irregularity of the bed of the river was also a factor. When these circumstances are considered, Old London Bridge may sustain a comparison with any of the masonry bridges of the present century.

When was the first effort made to span the Thames? To that question there can be no definite answer. ROACH SMITH, who was active in exploring during the excavations for the existing bridge, maintained that a bridge existed for use of the Roman settlement. London was not much valued by the Romans, for its military importance was of little account, otherwise we might conclude that from the mere interest of the constructive problem they would have built a bridge across the Thames as well as across the Rhine. Apparently there was no urgent need for a bridge,

and it is now assumed by many archæologists one did not exist in Londinum. There is no record about a bridge earlier than an Icelandic saga of the thirteenth century, which refers to a structure wide enough to allow two carriages to pass. It was, however, easily overthrown, for as we related recently, OLAF the Viking and his men tore down the props sustaining it in the time of King ÆTHELRED. The king must have erected another bridge or restored the old one, for he enacted that "whoever shall come to the bridge in a boat in which there are fish, he himself being a dealer, shall pay one halfpenny for toll, and if it be a larger vessel one penny." If we can accept the tradition preserved by the clergy of St. Mary Overy Church, and which JOHN STROW records, the first bridge in its origin resembled many others in Christendom:—

A ferry being kept in place where now the bridge is built, at length the ferryman and his wife deceasing left the same ferry to their only daughter, a maiden named Mary, which with the goods left by her parents, and also with the profits arising of the said ferry, built a house of Sisters, in place where now standeth the east part of St. Mary Overies Church, above the choir, where she was buried, unto which house she gave the oversight and profits of the ferry; but afterwards the said house of Sisters being converted into a college of priests, the priests built the bridge of timber, as all the other of the great bridges of this land were, and from time to time kept the same in good reparation, till at length, considering the great charges of repairing the same, there was by aid of the citizens of London, and others, a bridge built with arches of stone.

The stone bridge was commenced about 1176 by PETER, a priest who was attached to the church of St. Mary Colechurch, off the Poultry, and in which THOMAS A BECKET was baptized. There was then, as now, a Bridge House Trust, forming part of the Corporation, that possessed property. But the construction of a stone bridge across the Thames was in the twelfth century as costly an undertaking as the erection of a Tower Bridge with mechanical contrivances is in our day. The Corporation funds were inadequate. Contributions were sought, and among the donors were Archbishop RICHARD, who succeeded BECKET, and Cardinal DI PETRALONE, the Papal legate. PETER, the architect, gave his services gratuitously, and in addition erected, at his own expense, the chapel which was dedicated to the Canterbury martyr. HENRY II. imposed a tax on wool in order to raise funds. The new bridge appeared to be almost under royal control. King JOHN wished to have Father PETER superseded by ISAMBERT of Xaintes. The king also ordered that the profits of the houses should be assigned to the maintenance of the bridge. In 1212 they were destroyed by fire, and the Trust was crippled by the loss. HENRY III. seized the revenues, and after his death Queen ELEANOR insisted on her right to possess them. Towards the close of the century the bridge had fallen through neglect into a state of ruin, and its downfall was anticipated. EDWARD I. was prudent, and besides allowing the Corporation to have charge of the bridge and its revenues, approved of appeals towards its support.

The information relating to the early days of the bridge is not always vouched by documents, and if Mr. WELCH'S volume repeated only what is related in other books, it would not possess the peculiar interest it now has for antiquarians. From the end of the fourteenth century the history of London Bridge assumes a new aspect. Instead of mythic personages who appear to have cropped up at dates far apart, we have genuine citizens who exercised authority, and found it brought them trouble. The bridge was placed under wardens who were annually elected, and their accounts and other records, with some omissions, date from 1381. The facsimiles given by Mr. WELCH suggest that clerks were more artistic in the old days than at present. Some of the documents are works of art. It is a pity the griffin which was designed by JOHN NORMANVILLE, clerk of works in 1490, which appears on one of them, was not utilised by the Corporation when they resolved to erect the memorial at Temple Bar. It has the true heraldic character. The initial letters have the advantage of suggesting that they are distinctly penwork. The seals attached are often of historic importance.

What appears most interesting to us is the information about works and workmen which Mr. WELCH furnishes. In the account for 1494-95 we learn that 6s. 8d. was awarded to JOHN ISAAC, who had become blind and impotent, in consideration of his good and true service. Two surgeons

* *History of the Tower Bridge and of Other Bridges Over the Thames Built by the Corporation of London*, including an Account of the Bridge House Trust from the Twelfth Century, based on the Records of the Bridge House Estates Committee, by Charles Welch, F.S.A., Librarian to the Corporation of London, with a Description of the Tower Bridge by J. Wolfe Barry, C.B., M.Inst.C.E., Engineer to the Bridge, and an Introduction by the Rev. Canon Benham, B.D., F.S.A. Prepared under the direction of the Bridge House Estates Committee (Sir Albert J. Altman, chairman). Smith, Elder & Co.

are paid 58s. 4d. "for healing of a great wound in the head of JOHN ALERTON, carpenter, hurt at the bridge by default of the old gin." JOHN PATTESLEE breaks his finger, and 20d. is paid for curing it. Shoes, we find, were provided for carpenters working in the water, and gloves for masons and carpenters. At one time the masons employed at the windows are so busy they cannot go out for dinner; they are compensated by a payment of 6½d. We discover also that some workmen received commons, and that a steward and purveyor were employed to look after the comfort of the men. The relative value of labour in 1381-82 may be inferred from an account. The clerk received 20d. a week, six carpenters 22s., four masons 14s. 3d., two sawyers 7s., a mariner 2s. 6d., the cook and keeper of the dogs 22d., a carter 22d., a boy 2s., a paviour 3s. 4d., a plasterer and servant 4s. 6d.

The number of men belonging to the staff would suggest without further evidence that the bridge was hardly equal to sustain the wear and tear of traffic. As Mr. WELCH says, "The history of the bridge is almost a narrative of repairs." The roadway was so defective in 1425 it was necessary to prohibit carts shod with iron from passing under a penalty of 6s. 8d. The arches and piers were also liable to fall out of repair through the negligent guidance of hoys, barges and boats. There was a drawbridge between the sixth and seventh piers on the Surrey side, which was a continual source of expense, although it was of no more advantage than some of the opening bridges which the Board of Trade demand on lines of railway crossing shallow creeks.

The most efficient of all the causes which operated against the bridge was probably the rows of houses. Judging from the old prints of the bridge, they were higher than the majority of buildings in the City. The effect of wind acting upon so large a surface was transferred to the bridge and must have shaken the masonry. The shops and houses were a favourite resort, and as the Corporation was always tenderly disposed towards tenants, it was never decided to remove structures that were injuring the bridge. The difficulty of navigation is suggested by the fines which were imposed on sailors for injuries to the houses. In

1460 it appears there were 129 tenements on the bridge. A lease of 1613 describes a house in the middle west part as consisting of a hanging cellar, shop and counting-house attached, hall and chamber over the shop, a little dark chamber, kitchen, a little void room, a chamber behind, three little rooms over the kitchen and three other chambers. That occasionally the structures were of a gorgeous appearance is suggested by the description of one of the sixteenth-century buildings known as "Nonesuch House."

The chapel, which stood over the middle pier, was like some of those attached to palaces, and consisted of an upper and lower part. It was dedicated to ST. THOMAS A BECKET, on whose festival, as on Christmas Day, the chapel was attended by as many worshippers as could be packed within 60 feet by 20 feet. From what has been said on the subject it might be supposed the chapel was only an oratory, but Mr. WELCH has been able to prove by unquestionable evidence that in St. Thomas's Chapel services were held as in ordinary churches. It was occasionally employed for special services for foreigners. Mr. WELCH's description of the chapel is like one of the old illuminations, in which what is most essential in ecclesiology appears to have been introduced. The account of the latter days of the building will suggest the skill with which he has used the materials supplied by the records:—

In 1539-40 we hear the first knell of the chapel's approaching doom in the change of its dedication, 2s. being paid "to a paynter dwellinge in Southwarke for delasyng and mendyng of dyvers pictures of Thomas Beckett in Our Lady Chapell upon the Bridge." The clerical staff had become reduced to one priest and one clerk in 1541-42. In 1543 "a brotherer" (broderer) received 13s. 4d. for the "altering of the marterdom of Thomas Beckett into the image of Our

Lady." A law suit sounded a mournful anticipation of the end, and a committee of Common Council met to debate "concerning the staying of Ashley's suit touching the chapel on the bridge." The final sentence came in 1549. "It is agreid," runs a City minute of January 22, 1548-49, "that Mr. Wyllford and Mr. Judde, surveyours of the workes of the brydge, shall to-morrowe begyn to cause the chapell upon the same brydge to be defaced, and to be translated into a dwelling-house, with as moche spede as they convenientlye maye." For a year or two, nevertheless, the wretched remnant of the once beautiful edifice lingered on, being in charge of a watchman, Hew B'swell, who kept guard over the condemned walls at 2s. a week. In 1553 the

INITIAL LETTERS FROM THE REGISTER OF DEEDS RELATING TO LONDON BRIDGE.

agents of destruction appeared on the scene. Masons and carpenters take stone from stone and beam from beam. Labouers carry chalk and rubbish and boards, and make the place "clean"—a cleanness that might have drawn tears from the shade of honest Peter of Colechurch. The history winds up with this prosaic record. "1566-67. Received the 25th January, of Drewe Momperson, in part payment of 40 marks for a license to set over the lease of his house, the late chapel upon the bridge, for the term of years to come that was granted to William Bridger, grocer, his predecessor, deceased, 6*l.* 13*s.* 4*d.*

a boat on the water. The arch, it will be observed, is not Pointed. On the reverse is the martyrdom at Canterbury. "The Archbishop," says Mr. WELCH, "is kneeling before the altar, which is indicated by a lofty candlestick. His arms are raised and his hands joined in a posture of resignation. Immediately facing him on the left are two knights armed *cap-à-pie* in chain armour, each of whom is pro-

THE BRIDGE GATE IN 1616. (From Visscher's View of London)

There were probably many citizens who in secret were as grieved as the shade of PETER the architect. The memory of THOMAS À BECKET as a citizen and the son of a citizen was dear to the inhabitants. His image appeared on the various City seals, and, strange to say, it still survives (with St. PAUL) on the mayoralty seal. The ancient seal of the Bridge House, as will be seen from the annexed copy of an imperfect impression which is still preserved as one of the Corporation treasures, represented on the obverse the Saint enthroned above an arch of London Bridge, with

ected by a long pointed shield. The foremost knight is smiting the Archbishop on the head with a sword, the other is striking with a sword his companion GRIM, who is holding the cross. Above the knights is a star of five points."

From the importance of the bridge it is no wonder it was from an early period protected by gates and defences at the ends and near the drawbridge. The Southwark entrance was the more important point, and consequently, after the fall of the tower which stood there in 1436, we read how "divers charitable citizens gave large sums of

money" to erect another building, the charity being only another name for a desire to be secure. The new gate was destroyed in 1471 by FALCONBRIDGE. Its successor was more fortunate and endured till 1766. The appearance of the gate in 1616, with its ghastly crown of traitors' heads, may be judged from VISSCHER'S drawing.

It is not difficult to imagine the condition of the roadway of Old London Bridge. In 1669 COSMO DE MEDICI found it was almost impossible to cross owing to the number of vehicles, and the complaints about congested traffic were as general in the sixteenth and seventeenth centuries as they were in the nineteenth. Unlike the present bridge, there were attractions to tempt people to loiter in front of the painted and gilded booths, just as they still do in Cheap-side. In spite of its narrowness the bridgeway was constantly utilised for public receptions, and that may have been one of the reasons which made such lofty buildings desirable. Mr. WELCH supplies descriptions of many of those scenes, from which we extract the following:—

A novel spectacle attracted crowds to the bridge on April 15, 1413, the coronation day of Henry V., as will be gathered from the subjoined entry in the accounts:—"Divers expenses, steyning, painting, linen, cloth, and plates and other things for the giant, together with other workmen and chanters, with their apparel, on the coming of the king at his coronation to London Bridge, 9*l*. 13*s*. 10*d*." Two years afterwards a curt statement of expenses indicates that the bridge was decorated on the triumphal return of Henry from Agincourt, with the captive French monarch in his train. In 1421 the bridge resounded with preparations for again welcoming King Henry after his victorious

tenanted by pen or needle-makers, and economical ladies were wont to drive from the St. James's end of the town to make cheap purchases." A bridge in a City like London, which is always growing, should possess the quality of elasticity. Old London Bridge was not designed to meet the unknown requirements of a remote period, and any respect which might be given to it for its antiquity could not keep the citizens from feeling that neither the roadway nor the waterways were adapted to meet the traffic of London. The Corporation expended large sums on the structure, but when it was found that in 1811 the fall of water at times was no less than 5 feet, and in consequence lives as well as property were lost, it was plain the time had arrived for the removal of the old bridge. The history of the new bridge and of Blackfriars and Southwark bridges is narrated by Mr. WELCH, whose volume is the most important contribution to the history of London which has appeared of late years, or since Mr. RILEY'S "Memorials" was published. The pages are typical of the great City in which antiquity and modernity are combined to a degree that is without parallel.

AN IRON RESIDENCE ROOF.

THE new residence of John Jacob Astor, at Fifth Avenue and Sixty-fifth Street, New York City, fronting Central Park, occupies, says the *Engineering Record*, an area of 155 by 125 feet, and including the connected stable is almost a continuous building. The arrangement of main walls is that of three sides of a hollow square four and five storeys high, built of marble and brick masonry with iron and steel framework and girders, arched floors, flat and domed and vaulted ceilings on metal elements. It is covered with mansard roofs of 41-feet and 36-feet spans over the west and south street fronts respectively, a half mansard roof of 36-feet span over the north lateral part, and gable or deck roofs between and adjacent to these, 57 by 41 feet over the picture gallery, 40 by 35 feet over the stable and several smaller surfaces. All are of fireproof construction with stiff-riveted steel and wrought-iron trusses, girders, deep-rolled beams and framing, and slate, tile and copper covering. This covering has been carefully designed by a bridge and iron construction specialist to conform to the complicated intersections and irregularities of the finished structure, and also to afford required proportions and sections for the computed weights, loads and wind strains, as well as adaptability to modern shop practice, strength of connections, simplicity of detail and convenience of erection. The hips, valleys and rafters intersecting at all angles formed numerous complicated and intricate connections, each requiring distinct treatment. The main interior walls are of brick anchored firmly by iron bars to the outside walls at their points of juncture. These walls are furred with fireproof brick, of which also the lighter interior partition walls are constructed. The first four floors rest on the brick walls, while the fifth is in the roof. The floors are of steel beams 12 to 20 inches deep, and filled in between with flat burnt clay arches 8 and 12 inches deep.

The main roof is at an approximately uniform height and is U-shaped in plan, the base being in front, 114 by 41 feet, and the lateral parts each 125 by 56 feet, having at the corners of the front towers at the north-west and south-west extremities, each one 41 by 33 feet at the base, 33 feet high, and 21 by 13 feet at the top. These roofs enclose one 50 by 41 feet over the main hall, and have a mansard front both on the streets and overlooking the lower roofs of the inner square. The outer fronts are 25 feet high, and the trusses are designed to avoid producing any horizontal thrust on outside walls or columns. To this end the feet of the rafters are tied to the ends of the floor beams, which are intended to distribute any horizontal strains over the whole structure. The inside rafters extend to the 12-inch court wall, but are supported from iron columns so as not to load it, but to transmit the roof weight to the floor girders. The nearly horizontal top rafters have T-bar purlins 19 inches apart, which support terra-cotta blocks upon which the copper sheathing is laid. The steep pitched sides are slated on horizontal angle bars rivetted to the rafters 6½ inches apart. The main roof has a level ceiling throughout, formed of 2-inch blocks, resting in tees suspended from the tie-rods of the trusses. The stable roof is a single mansard similar to the north side of the main roof. The "suspended" ceiling is formed of 2-inch tees, spaced 18½ inches, attached to 3-inch angles every 5 feet, and which are suspended by bars from the rafters. The ridges between the flat and the steep roofs are covered with a copper cornice supported by angles bracketed to the rafters. The upper edge of the cornice is turned over and attached to the sheet-copper roof sheathing so as to be continuous with it. At the sides it runs down over a couple of

OBVERSE.

REVERSE.

ANCIENT SEAL OF THE BRIDGE HOUSE.

campaigns across the Channel. The giant's head was replaced by a newly carved one, images were repainted and gilded, stores of tinsel were purchased, gaily-coloured costumes of linen were prepared for bevy of maidens who should greet the hero; so great was the press of the work that artificers toiled day and night. In the spring of 1427 a similar excitement prevailed before the return of the great Duke of Bedford from the French wars. "Crokis" and "pastoral" sticks were purchased for idyllic scenes. Ornamental turrets were erected, and groups of juvenile choristers were trained to sing to the accompaniment of organs. The effigy of a princess, surrounded by attendant ladies, stood in a prominent position, and attached to the figure was an inscription consisting of David's words, "Dux itineris fuisti in conspectu ejus et plantasti radices." Twelve other effigies of celebrated personages were fixed on the bridgeway, and corresponding shields bore appropriate arms and names. The curious list of heroes deserves repetition:—Abraham the Patriarch; Isaac the Patriarch; Jacob the Patriarch; Joseph, Prince of Egypt; Moses, leader of the Hebrews; Joshua, leader of the sons of Israel; John, Duke of Bedford; Judas Maccabæus; the centurion of the Roman Senate; St. Alban the Prince; Henry I., Duke of Lancaster; Hector, Prince of Troy; Hercules the Prince.

As a contrast with the splendour and colour of the fifteenth century we have the description which PENNANT gives of the bridge in the eighteenth century:—"I well remember the street of London Bridge, narrow, darksome and dangerous to passengers from the multitude of carriages, frequent arches of strong timber crossing the street from the tops of the houses, to keep them together and from falling into the river. Nothing but use could preserve the repose of the inmates, who soon grew deaf to the noise of falling waters, the clamour of watermen or the frequent shrieks of drowning wretches. Most of the houses were

slates and is turned under and fastened back to the angle purlins.

The slates have a hole pierced through each side near the top, through which nails are clinched around the purlins, or copper wire ties are fastened. Each slate is set in cement above the exposed surface, and provision is made to drain off the moisture that collects between them through an iron pipe fastened to the hip rafters by bent clips and light castings and supporting the hip mouldings, the outside edges of which are also tied to the angle purlins. The rafters all rest at the bottom on a continuous cast-iron cill, at the outer edge of which a vertical webbed rolled channel is fastened to support the galvanised iron gutter frame, which is lined with copper, the copper passing up under the slate and fastened to the angle purlins. The dormer windows of the fourth storey have stone fronts on, the walls and terra-cotta blocks in the iron side frames, which are covered with slate or copper and have copper roofs. The large Fifth Avenue dormers have elliptical side windows 3 feet 9 inches by 2 feet 8 inches in each wall. Many of the fifth-storey dormers are semicircular in plan, and all of them are set entirely in the roof and are built with iron frames of angles and tees, into which fits an ornamental copper front that runs under the slates and covers the top and sometimes the sides.

The total amount of iron and steel in the building is about 700 tons. Mr. R. M. Hunt is the architect. The design, construction and erection of the ironwork was under the supervision of Mr. A. R. McKim, C.E.

TESSERÆ.

The Design of the Escorial.

THE foundations of the palace of the Escorial were laid in 1563, when the Baron Martirano being at the court of Philip II., and being much esteemed by that monarch as of acknowledged taste in the arts, he was consulted in respect of this important building, and commissioned to return to Italy to advise with the most celebrated architects of the day, Galeazzo Alessi at Genoa, Pelegrini Tibaldi at Milan, Palladio at Venice, and the Academy of Design at Florence. The grand duke Cosmo di Medici also ordered a design to be made by Vicenzio Danti. No less than twenty-two designs from different architects were collected on this occasion, but it is stated that none were so well received by the King of Spain and Martirano as that by Vignola, who, having had all the designs sent to him for his inspection and judgment, selected the best parts of each, and thus dressed up a description of olla podrida design for his most Catholic majesty. This at first sight does not appear to have been a very creditable proceeding on the part of the architect, but at this distance of time it would hardly be just to venture a censure without having all the circumstances of the case before us, and as the character of Vignola for honour and integrity has never been impeached, it is only fair to presume that he did nothing unworthy of it in this transaction. Philip invited Vignola to proceed to Spain to superintend the execution of his design, but finding himself advancing in years, and being much occupied with his professional duties (more particularly with those pertaining to St. Peter's), he prudently declined the royal invitation, and determined upon continuing in his favourite Rome. The Escorial, according to Milizia, was afterwards erected by Giovanni Battista, of Toledo, who commenced the work in 1563.

Early German Brickwork.

In the early examples of the brick style, the more elaborate parts, including the tracery of the windows and other moulded work, were executed in stone. Horizontal bands of stone were also occasionally introduced, and they have a good effect in tying together the different parts of the composition, besides their value in a constructive point of view. But in the later examples from the end of the fourteenth century stone is entirely dispensed with, and we find even such parts as crockets and finials executed in brick. The use of dark brown or black glazed bricks was also common during the later period. The character of the mouldings varies, of course, somewhat in the different periods, being simpler in the earlier, and more elaborately subdivided in the later. Delicacy of profile can hardly be expected from the nature of the material. Moulded bricks were also used to make up general forms, such as circular piers, the inner side of circular turrets, &c. There are a few points in the construction of the buildings which ought not to be passed over. There is usually a granite plinth carried all round the churches, and the towers are faced with the same several feet up. The absence of buttresses to the towers rendered it necessary to increase the thickness of the walls, which we find is very considerable, notwithstanding which they mostly incline from the upright, and it is remarkable that this occurs most frequently towards the south-west. The mortar joints are invariably very wide (from $\frac{3}{4}$ -inch to

$\frac{3}{4}$ -inch, or even more); the mortar itself is extremely hard. The construction of vaulting claims particular attention. In the first place, a light material was prepared in bricks, moulded of a wedge form. The ribs seem to have been first constructed independently as a skeleton, and between them the spandrels were filled in with the light bricks, apparently without the use of centreing, as each spandrel is considerably arched up to enable it to support its own or any superincumbent weight. Thus the vaulting rests entirely on the ribs, which are not tailed into it. It is a single brick in thickness, about 6 inches, and is backed up only a very short distance above the springing, so that the form is very distinctly seen on the upper surface, where it presents a very remarkable appearance. The bond used throughout is the Flemish, or, as it is now called, the cross-bond. The arches are always built in half-brick rings. The bricks used in the buildings are of a larger size than those now commonly used in Germany. They are remarkably hard and sound, and are rather heavy. Though externally of a brown red colour, the inside is grey, like our stocks. This is not the case with those now made. The light vaulting bricks were made with a mixture of chopped straw, so that when burnt they were porous, but of sufficient strength for their purpose. The first-class bricks, as a material, are superior to those used in this country; the colour uniformly red, except where a vitreous action had been produced in the burning. There did not appear to have been a rubbing down of the face of the material when used for mullions or tracery—the ordinary examples presented too rude a surface to suppose such an operation.

Gas Lighting.

In 1792 William Murdoch employed coal-gas for the purpose of lighting his house and offices at Redruth, in Cornwall, and this appears to have been the first idea of applying the light to useful purposes, although the gas had been discovered and obtained both naturally and artificially more than half a century before. He had also a gas lantern in regular use for the purpose of lighting himself home at night across the moors from the mining engines that he was erecting, to his house at Redruth. This lantern was formed by filling a bladder with gas and fixing a jet to the orifice, which was attached to the bottom of a glass lantern, the bladder hanging underneath. After various experiments, whereby he proved the economy and convenience of light so obtained, he made a public exhibition of it by lighting up the front of Boulton's manufactory, at Soho, on the occasion of the general illumination for the Peace of Amiens in 1802. He subsequently lighted up some cotton mills at Manchester, beginning with that of Phillips & Lee; and he published a paper describing the advantages in the "Philosophical Transactions for 1808," for which the Royal Society presented him with their large Rumford gold medal.

The Mole of Hadrian.

Procopius is the first who gives any description of what it was, in his account of an assault made by the Goths outside the Aurelian gate (that is, not far from where the Imperial Gauls of 1849 made their assault). He thus writes:—"The tomb of the Emperor Hadrian is situated outside the Porta Aurelia, about a stone's cast from the bulwarks of the city; it is an object worthy of admiration. It is built of Parian marble, and the blocks fit close to one another without anything between to fasten them; it has four equal sides about a stone's throw in length; it rises above the city walls; on the top are statues of the same kind of marble, admirable figures of men and horses. The men of old time (that is, the Romans probably in the time of Honorius) joined this monument with the bulwarks of the city by two walls, because it appeared advantageous for the defence of the city; it thus became a part of the fortifications and had the appearance of a lofty tower covering the entrance of the city." So far we learn that the mausoleum was converted at a very early period (for Procopius saw it in 534 A.D.) into a fortress. Those beautiful statues, however, which the Secretary of Belisarius describes, were put to a strange use by the defenders of Rome. Instead of more appropriate missiles and more raw material, these masterpieces of sculpture were torn from their pedestals and hurled upon the besiegers below, and perhaps the breaking of the head of a Goth might cost a whole Venus or a Mars, a head of a Faun or a foot of Hercules. What are we to say of a passage cited by Salsmasius from John of Antioch, who lived A.D. 620? "The figure of Hadrian," he says, "stood on the top in a car drawn by four horses, of such colossal dimensions that a full-grown man might pass through one of the horse's eyes." A chronicler of the thirteenth century, commonly called the Anonymus, says that the tomb was faced with marble, and he talks of gilded peacocks and a bull. The same Mediæval sightseer mentions also bronze doors and horses, which he saw about the mausoleum. But the earliest representation or drawing we have of the Mole is that now existing on the bronze doors of St. Peter's, made in the days of Pope Eugenius, by Antonio Pollagio, about 1481.

In Camucci's sketch, made a century later, some of the cornice is indicated which he must have seen, and which he says was embellished with ox heads and festoons, and on the frieze there were two inscriptions then to be seen belonging to Commodus and Lucius Verus. Pope Clement VII. and his architect Labacco gave currency to the tradition that the beautiful columns of pavonazetto, which stood in St. Paul's Basilica, once adorned the upper storeys of this mausoleum. Now with these notices of historians and artists of old time, added to our own observations of its present state, we are to make the description, both external and internal, of this durable monument. The mausoleum was formed of a square basement, which measured 253 feet on each side, making a perimeter of 1,012 feet. The door, or entrance, was in the middle of the south side, facing the passage across the bridge. At the four angles of this solid basement were colossal statues or trophies—we may suppose them to have been those horses which are mentioned by the monk of Antioch; in the centre of this massive foundation, which was adorned by festoons and bucrani, rose the round tower, which still, in a great measure, exists and serves as the donjon or keep of the castle. This tower did not diminish towards the top as some have supposed, for Procopius measures the diameter at the top by the same expression of a stone's cast as he measures it at the bottom; though diminished by all the marble facings in width, it still yields a diameter of 188 feet. The round mass was compacted together of peperine stone and the usual materials employed in solid Roman works, but it was all faced with square blocks of Parian marble. We must accede to the generally received opinion that two magnificent colonnades went round the monument, dividing it into two storeys, and that statues stood in the intercolumniations. Those statues were probably *chefs-d'œuvre* of art. The famous Barberini Faun, which was found by the pontiff of that name in a ditch of the fort, is a specimen; the Dancing Faun in the Florentine Gallery is another; these had either fallen from their place or had been used by the troops of Belisarius for overwhelming their assailants.

The Balbi Palace, Genoa.

One room, about 20 feet square, which serves as a sitting-room, is very beautiful. It has one large gold cornice with ornament tinted brown, a vaulted roof; the frieze is large and painted with richly coloured designs of figures, centaurs and women, dark and rich in the Venetian style. In place of an architrave there is a large ovolo moulding, also gold. The walls are of bright red, or rather dragon's blood. The pictures have plain gold frames; the doors have a golden canopy, from which hang dark red velvet hangings, plainly hemmed with a border of the darkest stuff (red); there is a die all round of which the general tint is light brown, and a golden cyma moulding runs round it and doors into red wall; there are two windows. It is remarkable that this room when seen in the heat of summer does not look hot. The groined roof with its allegorical figures is, however, faulty.

House-Painting in the Seventeenth and Eighteenth Centuries.

In 1671 it was agreed that the wainscot in the hall of the Carpenters' Company should "be handsomely painted, and the walls above the wainscot on the south side hung with painted cloth of some neat painting work suitable to the front side." A French traveller in England in 1672 remarks that "the houses of Canterbury are well built and painted after the Dutch fashion." For many years after 1700, the following description from a work of the period will convey some idea of the extent of painting practised. "Outdoor painting for doors, shop-windows, window-frames, pediments, architraves, friezes and cornices, and all other exposed timberwork, ought at first setting up to be primed with Spanish brown, Spanish white and red lead (about a fifth part) to make the other two colours dry, ground in linseed oil; then again with the same colour, only whiter; and lastly with fair white made of lead, and about a fifth part in quantity (not weight) of Spanish white." "Wainscot colour," "white colour" and "walnut colour" are enumerated; also "ordinary branched painting" and "plain japan, either black or white." On considering this recital of painter's work we may assume that these wainscot and walnut colours were used for the purpose of making woodwork resemble those woods. An interesting account has lately been published of a lady of rank, who in 1612 or 1613 appears to have entirely changed the fashion of the arrangements of houses in France, and to have been the first who painted rooms in any other colour than red or tawny. The next and last item in the description is "whiting and colouring on plasterer's work." The combined use of "colour" (distemper) for interior work, down to so late a period as 1700, accounts for the extensive use made of it in our churches. It is clear that from about 1700 oil paint became a disguiser of materials, and we know from his own description that the interior of St. Paul's Cathedral was painted under Sir Christopher Wren's direction. In a work of 1703, the contrivance of closets in most rooms and painted wainscot are mentioned as two great improvements. Perhaps

the first intimation of oil paint being used to a large extent internally is in a "Compendium" of 1721. It states that the taking of the dimensions for painters' works within doors is the same with that of joiners', by girtings about the mouldings and members of cornices, &c.; but the painter never requires work and half work as the joiners do, but reckons his work once, twice, or thrice primed or coloured over. Wood, in his History of Bath, says "that about 1727, if the walls of any of the rooms were covered with wainscot, it was with such as was mean and never painted;" as the new buildings advanced the rooms were all wainscotted and painted in a costly and handsome manner. Ware, in 1767, writes that "fir, as it is cheap and works easy, since the use of paint has become so frequent, has in a manner superseded all other kinds." In the descriptions of buildings given at the end of his work, he specifies that the walls are to be rendered and fronted for hangings, and paints all the wainscotted rooms a "common or stone colour" three times in oil. In 1775 a large mansion in the country is stated to have paper to the ground-floor rooms, whilst the walls of the bedrooms, garrets and basement were limewhited. And at the beginning of the present century, says a later writer, the houses of traders and middle classes, particularly in the provinces, were chiefly adorned with simple washings of rose pink, whitening and size. A friend, now in his eighty-fifth year, remembers the lining to walls being left unpainted, and much of the woodwork even to the rooms connected with the Houses of Parliament was also of plain deal. The plastered walls of houses were coloured, the sashes painted white, the door-skirtings and other parts generally black. Several people can no doubt recall many houses in the country still exhibiting this ancient style of ornamentation. Thus we may conclude that house-painting, or, as it has been very descriptively termed, the "three coats and flat work," did not come into fashion until about the period of William and Mary, and Anne, up to which time either colouring by distemper or by whitewash had been in vogue for plasterwork, leaving inside woodwork more or less untouched.

Geometrical and Decorated Tracery.

The first impression conveyed by a Geometrical window and a Flowing Decorated window, side by side, is that while the former is obviously drawn wholly with the compasses, the latter seems at least to be drawn in some degree *libera manu*. Perhaps this impression, so far as the Flowing Decorated is concerned, is hardly correct; but there is little doubt that it results from certain appreciable causes, and indicates a real difference of principle in design. Take the simple Geometrical and an equally simple flowing two-light window. The eye at once detects the use of the compasses in the one, and the very centres from which the curves are struck; in the other no single curve is sufficiently simple to be referred, except with considerable effort, to its centre or centres; it seems, indeed, to be drawn without any mechanical aid. Take more complex arrangement, and still the same character is found carried out through 3, 4, 5, 6, 7, 8, 9 lights. This alone, it seems, is sufficient to demand a separation of the two styles; for in speaking of design, this very fact, that the designer is put into so different an attitude as that of one who is limited wholly to geometrical forms, and of another who allows himself, or seems to allow himself, the license almost of a sketch, is surely enough to separate between them. But the free hand of the later designer had its rules too, and those rules were apposite to those of his predecessors. In designing a Geometrical window the architect adhered to true circles, or parts of true circles, never flowing off into another curve struck from another centre. The ogee was unknown. Cusps were of circles, or parts of circles, struck from circles within the greater circle, independent of one another, but with absolute dependence on the centre of the first circle; these points were cut off by another circle, concentric with the first, or that which circumscribed the whole figure. Hence a transparency of purpose and a precision of effect in this style never afterwards attained. All is complete in itself, and each member perfect, either as a part or as a whole—a character which Professor Whewell abundantly recognises when he calls the Geometrical Complete Gothic. It must be confessed, however, that something of sameness and of restraint resulted from the use of the compasses, restricted by so narrow laws. This was remedied in a subsequent development of the same style, which let in far greater variety, sometimes amounting almost to license. Indeed, though the forms must have often struck us with surprise and pleasure, they have never yet been fully appreciated. Mr. Sharpe, in his work on "Decorated Tracery," alludes to them thus equivocally:—"Towards the close of the Geometrical period there occurred some attempts at originality in the designs of window tracery. Becoming apparently dissatisfied with the extreme formality of the usual geometrical forms, several fanciful experiments were tried by the builders of this period, which, without betraying any symptoms of impending change, present—under forms which may still be termed Geometrical—very little similarity in their general outline to the (former) examples."

ST. NICHOLAS CHURCH, PYRFORD.

ST. NICHOLAS CHURCH, Pyrford, Surrey, is a small building of stone in the Early Gothic style, consisting of nave, chancel, north porch and low western tower of wood with spire. It is picturesquely situated on a mound, from which can be seen a charming panorama of Surrey meads intersected by winding rivulets, in the centre of which are the ruins of the antique Newark Abbey.

It is a small building of flint and ironstone rubble-work, with dressings of chalk and firestone. It is in plan scarcely altered from the form in which it was built towards the end of the twelfth century. The side windows of the chancel (one of which has been altered externally in later times), the chancel arch, the north and south doors of the nave, and the two small windows in the west end all belong to this date. Of these features the north door alone is ornamented, the others are extremely simple. The north doorway is designed with zigzags in the arch and detached shafts in the jambs, one of which alone remains, the other having

other woods, and framed with carved oak styles and rails. On the front panel are the initials N. B. and the date 1628.*

Before the late restoration the pulpit was covered with thick white paint; much of the carving and all the inlaying were discovered when this was removed. The base having disappeared, a new one has been supplied. Some decayed panels also have been restored.

The only specimen of old glass remaining in the church is that which fills the quatrefoil in the end of the fifteenth-century east window. It represents the Holy Trinity, and appears to be nearly, if not quite, coeval with the tracery of the window.

Throughout the church during the restoration were found traces of painted decoration. A few figures and ornaments were saved, including two consecration crosses in the chancel and one in the nave.

Two systems of decoration were observable, corresponding with the dates when the church was built and restored. The later system being on a tender coat of whitewash, none of it could be preserved. Its removal exposed the earlier

been cut away to form a story in later times. The church seems to have been thoroughly restored in the fifteenth century, when two-light traceried windows were inserted in the east end and the side wall of the nave, replacing no doubt small early windows. At the same time the present massive roofs were constructed, also the oak pews, of which, when the church was restored a few years ago, the greater number were repaired and kept, though sadly mutilated by the addition of high tops. The simple and beautiful north porch belongs to this date.

The canted roof of the nave seems to have been originally open to the underside of the tiling, except that the wall plaster was continued up the first or vertical cant till it met the tiles. That this was the old arrangement is evidenced by the traces of colour found on the upright plastering, and also by the evidence of the panelled ceiling.

At the eastern part of the nave roof exists a canted or waggon ceiling covering the three end rafters, formed of wide feather-edged and grooved boarding nailed to the underside of the rafters, and bordered with simple battlemented mouldings. It is painted with yellow flowers and rosettes on a red ground. The pulpit is a very beautiful Jacobean work, formed of simple deal panelling inlaid with

system of decoration painted on a harder plaster. The original drawing was exhibited in the last Black and White Exhibition.

THE death of M. BIDA, whose fine illustrations of the Gospels are appreciated in England, has caused the revival of a story connected with one of his drawings. In 1867 he exhibited a drawing in the Salon called *Solomon's Well*. It was purchased by a dealer for 6,000 francs. Soon afterwards, Baron JAMES ROTHSCHILD expressed a desire to possess the drawing, and told the dealer to fix the price for it. The dealer declined to sell it, but he offered to present it to the Baron on consideration that his admiration for the drawing should be expressed by sending a cheque for 2,000l. to the artist. The arrangement was faithfully carried out. ALEXANDRE BIDA was one of the most refined draughtsmen of the century. He ought to have gained a high position as a painter, but he had a natural aversion to colours. He died in his eighty-second year.

* It is not known who N. B. was, as the registers only go back to 1666.

ILLUSTRATIONS.

THE HISTORY OF CLOVIS.—NO. II.

THE second compartment of M. JOSEPH BLANC'S work in the Panthéon depicts the renewal of the battle which, according to the legends, changed its character owing to the co-operation of the heavenly warriors. The artist has not attempted to give a symbolic character to the incident. Battle-pieces rarely resemble battles, but the picture within a limited space and with a very few figures is a suggestion of a fierce onslaught.

HALLYBURTON HOUSE.

THIS building was designed for Mr. ROBERT STEWART MENZIES by the late Mr. ANDREW HEITON, of Perth. It was completed at a cost of 13,000*l*. A view of the banquetting-hall has already appeared in *The Architect*.

COUNCIL CHAMBERS, PERTH.

THE Perth Municipal Building was another of Mr. HEITON'S works. Although it has the effect which is needed in a town having so much historic interest, the outlay was moderate, being only 13,000*l*.

THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Association was held on Friday evening, Mr. F. Hooper in the chair. Mr. C. G. HARPER read a paper on

Architectural Illustration.

In the course of it he said:—Illustration has in these days become so widespread that the pictorial presentment of every imaginable, and indeed of every inconceivable, thing is taken as a matter of course and as the daily routine in places where, but some fifteen years ago, pages of written description would have been devoted to the explanation of a subject—and even then with but indifferent success.

It is not, however, upon illustration as a whole that I would address you to-night, but only upon that branch of it comprised within the title of this paper. And in addressing you upon one of your very own subjects, I feel that for one who, like myself, is not, nor has ever been connected with your profession, the uttering of opinions before so technical and specialist an audience as this might easily be construed as an impertinence, were I not at once to repudiate anything that savoured of architectural authority. Therefore, I pray you be minded that although by reason of experience I claim the right to speak upon "process" reproduction of drawings, yet it is only with the greatest diffidence that I venture to address you upon actual draughtsmanship or the vexed question of style.

Since the first introduction of the perspective sketch into the work of architects' offices and into the pages of your professional newspapers, the question of style in drawing (and more especially in architectural illustration) has been always more or less under discussion, but never, perhaps, so constantly as now. I have ventured, in the pages of a technical treatise upon "Drawing for Reproduction," which I have been guilty of writing, to remark that this is, in a peculiar sense, pre-eminently the age of the picturesque, and if I repeat that remark here, it is because what was meant for artists in general in the pages of that book may most fitly be re-echoed in this place before a gathering of architects, to whom the picturesque, and the demand for the picturesque, mean much. Gentlemen, I begin to hate that poor battered word—knocked out of all real sense meaning nowadays—as much as you doubtless have hated it for some years past. For the architectural profession the picturesque has meant a wild riot of crow-stepped gables, perilous-looking pinnacles and all the crazy apparatus of the moated grange. Now the moated grange, the survival of the centuries, that lovely time-mellowed jewel of our shires, is a beautiful possession, and its charm is not to be over-estimated; but its braggart ready-made imitation, whether in architectural design or in periodical illustration, is nothing less than a miserable affectation. We will not stop to consider whence comes this strange craze—whether we owe it to the Christmas numbers of years since, or to what else—but we may deplore the intrusion of this so-called "picturesque" quality into the architectural illustration of to-day.

Years ago when the measured elevation was the utmost that your professional papers attempted in the way of illustration, the artists among you groaned in spirit at these bald and altogether artless productions of the architectural drawing office, and sighed for perspective views. Well, nowadays you have your perspective views—and the picturesque is cheap to-day. Architectural illustrators, lay or professional, whether

they be working for a technical audience or for public approbation, will be romantically "picturesque," no matter what their subject. The spirit and feeling of any particular subject, truth, reticence, dignity, and every sober quality may go hang, so only they may run riot in "picturesqueness." They have made the appellation hideous; so much so, indeed, that if you forgive me the frequent employment of that offensive term, it will be no little exercise of charity that urges the absolution. It is, however, by iteration that I would draw your earnest attention to the enormity (no less a term will serve my turn) that falsifies architectural illustration, until nine-tenths of the work done to-day is arrant and ill-judged convention. Restraint is at a discount in illustration and design. The eye is wearied and the senses stunned with the picturesque, and should your modern illustrator, by some unkind fate, have professional relations with that place of despondency and despair—I name Gower Street—he will render that depressing thoroughfare as a very Nuremberg for picturesqueness. Perhaps you will say "all praise to him for so stupendous an achievement," and I would allow the *tour de force*, but not the morality of it. I saw but the other day an illustration of an exquisitely simple, and yet most striking, house in Queen's Gate, a modern house doubtless familiar to you as architects, a house which even a layman, like myself, can identify with Mr. Norman Shaw. That house, in its Georgian restraint and precision, its four square red-bricked walls and its green-shuttered windows, wears a noble and stately look that puts to shame the stuccoed respectability of the '60's across the way. Quiet dignity is the note of that house, but the frantic draughtsman who illustrated it revelled in spots and blots and a romantic decrepitude that deprived the architect of all the credit due him for his reserved force, and left no vestige of quiet there. This class of draughtsmanship is almost exclusively penwork, and it had at one time the merit of a cunning use of black and white. To Mr. Herbert Railton, with whom it originated, belongs the credit of using the pen with vigour and effect; but in these days the excesses of this manner and the convention in which these drawings are executed would lead one to believe everything was going up to kingdom-come in a dynamite explosion. They have already brought it into discredit.

This is no plea for a bald and merely matter-of-fact style of drawing. Some of your most distinguished architects have wielded a most poetic pencil, and one cannot object to poetic feeling in draughtsmanship. Only, no one requires the high-strung epic flights rehearsed by these extremists.

While art remains a matter of temperament and individuality (as it must ever remain), I would urge you to seek your own salvation in methods of expression, and to take no man's advice as to the style and manner you should adopt in drawing. The world is echoing with advice of one sort and another to-day, and because so many take these hints and precepts for very gospel, much of our modern work is so unoriginal and hackneyed. Better be damned for one's very own sins of omission and commission than for the mistakes of others. For see the folly of it. One man may as readily as another listen to the views and appreciations uttered here and printed there and repeated somewhere else; and should one do so, why not an hundred? And so round the same vicious circle of copyism and hero-worship. At no other time was there so much good work produced as now, in all sorts of departments, and, for the matter of that, at no other period has there been such a tremendous output of the vilest work. But singularly enough, the worst is the most insistent. It rises, like scum, to the top and flaunts itself in the most public places and becomes, with the artless, a model for repetition. Whack one of the objects of your hero-worship and he roars like the bronze Buddha at South Kensington, and for the same reason—that he is hollow and empty. Let every man be his own hero and a law unto himself. First, however, you must learn the grammar of your art, so that you do not transgress its fundamental rules nor exceed the limits of a particular medium. Originality is one thing, license quite another. I do not urge you to be original in order that you may produce something as stupendously shocking in illustration as George IV.'s Brighton Pavilion was in design. The originality that reared either that or the Savoy Hotel—that hideous caravanserai upon the Victoria Embankment—is altogether to be deprecated, and the man who designed Queen Anne's Mansions deserves, I take it, nothing less than eternal contumely at your hands. And let us always bear in mind that each medium has its own peculiar and inimitable strength; that a pen drawing cannot and ought not to compete with wash, crayon, or pencil; nor for that matter should etching be brought to imitate engraving. Processes other than lithography have hitherto had little interest for the architectural draughtsman, for his work has been chiefly reproduced in the pages of his technical papers, and they as already mentioned use chiefly that one method. But now that all kinds of process work are becoming cheaper, it is not unlikely that in the near future these papers will use a larger variety of methods than they have done hitherto. At any rate, I judge it will be of interest to show some reproductions of pen

drawings made for book illustration, and have hung here some six frames that exhibit at one glance the drawing and the reproduction. Here are drawings made with ebony stain upon paper and cardboard, and reproduced by line processes and by tone. Most of these drawings are made with a pen, and I have selected them especially because I think line-work is of more interest to you than wash.

Here is an essay in the application of the mechanical tint known as "Day's Shading Medium," an invention which may be succinctly indicated by saying that the shaded effect is produced from engraved sheets of gelatine bearing a close concourse of dots in relief. These gelatine sheets, when inked up with a printer's roller and pressed with thumb and finger upon the zinc plate on which the drawing is etched, produce the dots you see eventually upon the print. You have, however, nothing at all to do with that, but simply indicate to the process man by scribbling in blue pencil (or making a blue wash) on your drawing where you intend these dots to come.

But now to leave tints and come to quite a different matter. You will have noticed, no doubt, that the process man (and indeed many writers upon this question of reproduction) insists upon your drawing for line-process with as clear and sharp a line as possible. He will not hear of your leaving pencil marks upon your paper, but will tell you that every trace of pencil must be carefully removed before he can attempt to make a block from the drawing. Paper, did I say? Nay, he will not hear of the draughtsman using paper, but only cardboard of the whitest and smoothest variety. Now, this, of course, is done chiefly to make his work the easier, and in order to produce blocks that may show a sharp, clear line. Of course, there are many kinds of drawings where a line of this description is desirable.

At the conclusion of Mr. Harper's paper, Mr. F. T. W. Goldsmith read the following communication which had been received from Mr. Phené Spiers:—Whilst I agree in the main with Mr. Harper's interesting arguments, which deal with architectural illustration, as the paper is read before a society of students, I should like to point out that it does not necessarily follow that the class of drawing which is likely to be indulged in by the student on tour is that which lends itself well for illustration. I say it does not necessarily follow, because I recollect that one of the first and best publications in black and white was that which was produced in 1858 from the drawings of Mr. Norman Shaw, the result of his work as travelling student of the Royal Academy. These drawings, however, were not made for the purposes of publication, and it was only on his return that he was persuaded to allow them to be reproduced as architectural illustrations. I have never seen the original drawings, but it is possible that the lithographic reproductions were worked up to some extent to make their publication more popular. Now, I take it, the principal object the student aims at when making a sketching tour is to learn how to draw art, how to observe, and if he once gets into his head that there may be a third object, viz. that of publishing his drawings, he runs the risk of neglecting the first two. The accidental effects of fleeting shadows, the careful blacking-in of every brick in shade, and the picturesque effects of broken stone-courses exercise such influence on him that he has entirely forgotten the architectural design of the building he has drawn, and is only able to console himself with the reflection that he has, at all events, turned out a very pretty drawing, which is the admiration of all his brother students (and perhaps his lady friends), and will also do admirably for publication. I do not wish to discourage the student who desires to add to his laurels by the execution of drawings which will give him a chance of carrying off the prizes in the Architectural Association studentships, or adding to the value of the Architectural Association sketch-book, or of assisting in the illustration of architectural drawings in our professional journals. In fact, on the contrary, I not only consider such aims perfectly justifiable, but I think it may excite the student to much more serious work than he might otherwise have attempted. I do, however, lay great stress on the fact that his first and main object is to learn. That object may be attained in two ways, either by measuring and plotting on the spot, or by careful delineations of perspective drawings. The first method has been quite discounted by the reader of the paper, who even objects to the use of the T-square in the making of the perspective drawings. I think the student is justified in making use of any assistance in that way, provided that he does not become the slave of his drawing instruments. There are many buildings the distinctive character of which mainly depends on the absolute regularity of their vertical and horizontal lines or the parallelism of others. Excepting half-timber houses and other such picturesque structures, are there any which do not? And why should the student forego all the training he has received in the office and laboriously try to work without the ordinary instruments of the craft? Even with the T-square it is possible to draw an artistic line without taking to the expedient which the late Mr. Joseph had resorted to in Pugin's office, viz. notching all the T-squares,

or cutting pieces of cardboard in gentle curves to give a flowing line to the tiles of a roof. There are two types of drawing I would recommend to the attention of students about to travel. The one is that which was pursued by the late Mr. Wm. Burges, the other that of the late Mr. George Edmund Street. Mr. Burges happened to be very short-sighted, and was obliged to use opera-glasses to see at a distance. This made it difficult for him to make perspective drawings. He set to work, therefore, to measure and analyse the construction of the buildings he came across. He was not content with the external appearance; he virtually dissected a building or some distinctive feature of one so as to see how it was put together. On one occasion he measured portions of the choir of Beauvais, on another the flèche of Amiens, I think, both stupendous structures, which show that his short-sightedness did not interfere with his powers of observation. He took up any phase of art workmanship, and Mr. Krall, the ecclesiastical worker in metals, told me that Mr. Burges's designs for chalices, &c., were absolutely perfect, and showed in detail how every part was to be put together. Mr. Burges was led eventually to publish his drawings, which are in the library, so that you will be able to take note of his field of work. Mr. Street was the most prolific sketcher we have ever had. I met him once at Mont St. Michel, when he told me that he had measured the plan and made a perspective drawing of the choir of every important church in Europe. On a previous visit to Mont St. Michel he had not been able to get inside the church, as it was used for a prison, so that then he had to return (in 1880) to complete his series. I am not aware that he ever made use of his sketches; his object was to impress the buildings on his memory and to penetrate into the thoughts and reasonings of the Mediaeval builder. His sketch-book measured $8\frac{1}{2}$ inches high and $6\frac{1}{2}$ inches across, and he frequently drew across the two pages. He always drew freehand and never used india-rubber. This, however, necessitated far greater care in the first setting out. He was extremely careful in the profiling of his mouldings, the mass of which was always proportional to the structure as shown in his drawing, and he contented himself with only drawing one or two lines through. I published one of the drawings in my book on "Architectural Drawing," his son having kindly lent me the drawing for that purpose. I had to trace it for reproduction, so that it loses some of the artistic value of the original. It represents the tower of Andrieu Church in Normandy, I think, and although it is in perspective virtually, for the student it is worth more than a $\frac{1}{4}$ -inch scale drawing. Mr. Street's drawings were purely architect's drawings and would probably be quite unintelligible to an outsider. There is no doubt that he was passionately fond of drawing, but his main object was to store facts in his memory, which I recommend to the serious attention of students as their first consideration. If at any time any of you should wish to turn your drawings to account, then I would ask you to look through Mr. Prentice's work on Spain. In that case the drawings were made for the purposes of publication, but they are distinctly architect's drawings and probably do not appeal much to the general public.

Mr. J. PENNELL praised magazine sketches. Ruskin's drawings of architecture he admired. Mr. Mitchell's drawing of Durham Cathedral he thought was abominable. There was no light or shade. The architects of old cared for light and shade. He and others like architects strove to do what was right in architectural drawings, and took trouble in making their perspectives give an architectural drawing that all could appreciate.

Mr. W. S. WEATHERLEY said he hardly understood the drift of the subject of the paper, as it had been so wandering. They could not combine in one drawing what would make a picture, and at the same time satisfy an architect in detail.

Mr. HART expressed disagreement with Mr. Harper as to the two illustrations of the White Hart Hotel.

Mr. E. GREENOP proposed a vote of thanks to Mr. Harper, and said he had not quite understood what Mr. Harper's grievances were. Some of a series of cathedral illustrations that had been published were past praying for. He (the speaker) condemned illustrations that lack all artistic feeling by reason of giving too much attention to minutiae of detail.

Mr. H. RAILTON was surprised that Mr. Harper should dare to speak of architecture. Few persons could construct architecture on paper. Many a person might suppose he could draw architecture, but few could show construction in two lines, of a Tudor, Geometric or Early English period. There were persons who could do it—Mr. Millard, Mr. Horsley and several others, men who had been trained in an architect's office. As an artist, Mr. Pennell drew architecture pictorially; they, on the other hand, drew it as architecture. Those who lacked the grip and knowledge of architecture had no right to dictate to architects about architectural drawings, though architects would welcome criticism from trained architects.

Mr. J. OSBORN SMITH said that accuracy was necessary in architectural illustration. No meritorious part of architectural drawings was more gone against by popular artists than

accuracy—false representations of the originals without beauty.

Mr. GOLDSMITH having seconded the vote of thanks, it was put to the meeting by the Chairman and passed.

Mr. HARPER returned thanks, but did not reply to the strictures that had been passed on his paper.

SIR C. L. EASTLAKE ON THE DECORATION OF HOUSES.

(Concluded from last week.)

Drawing-room.

BUT the choicest works of taste should unquestionably be in the room most occupied in hours of calm seclusion and leisure; and in order to find wall enough for the pictures, this may be assumed to be the principal drawing-room. Here, therefore, may be the best specimens of painting, and even of sculpture, if the space permits; here the chimney-piece may be by Flaxman and the doors of the print-case by Stothard. The pictures cannot be very large, on account of their number and the size of the room. This, the objection which in a great measure excludes the grandest works from our dwelling-houses, was met by the Italians, and by Nicolo Poussin, by reducing the grand to domestic conditions. If you have only small pictures, however, you cannot cover the upper part of the walls, for you are not supposed to have any work of art here which can be sacrificed.

Enlightened connoisseurs see excellence both in the Dutch and Italian schools, but they are often embarrassed in arranging them together. I am convinced, however, from instances I have seen, that this is to be accomplished satisfactorily. It is sometimes argued that no one reads Milton and Crabbe alternately; but this is hardly a parallel case. Many go to a gallery to look at a particular picture and see nothing else; the eye is blind when the attention is not actively exerted. So in a room, the spectator selects his favourites—his favourites at least for the time and scarcely looks beyond them. At another moment he will perhaps direct his undivided attention to works which he passed over on a former occasion. A certain congruity is sometimes to be accomplished, by attending to impressions rather than names and schools. Many an Italian picture would not be out of place with the Flemish and Dutch school; while Vandyke, Ruysdael, Cuyt and others might sometimes harmonise in many respects with the genius of the south. The arrangement of pictures comprehends some of the difficulties which the artist experiences in the production of one; for a certain balance and repose are as essential for the eye as an harmonious impression for the mind. Much must, therefore, depend on the nature of the materials; and the (assumed) different character of your two drawing-rooms may here be an advantage.

You, I know, will not ask whether the productions of the English school are admissible in this "Tribune" as well as elsewhere. Such is the variety of English art that the more refined Dutch, the Flemish and the Italian taste may be recognised in it by turns, and no modern pictures harmonise with the scheme of colour and effect which characterise the master-works of former ages so well as the English of the last century. Thus much of schools, and those we have not mentioned may be tried by the same tests.

With regard to subjects, the mind as well as the eye must be respected; the *ethos* of painting is quite compatible with familiar and homely subjects; and, on the other hand, the greatest Italian masters have sometimes sought for poetic impressions in regions where it would be unsafe to follow them. But, with this reservation, you must not be exclusive; various minds, or the same mind in various moods, will like variety of aliment. In other situations which we have had occasion to consider, the subject has been in a great degree calculated on the probable feelings of the spectator; here the subject is independent, because the attention is free, and the whole art appeals by turns to the whole range of thought. The leisure of cultivated human beings should be so far complimented as to assume that all the strivings of the mind are worthy to be ministered to. It is a mistake to suppose that solemn or even terrible themes are always objectionable; I believe it will be found that the grander efforts of invention (I speak of works by the ancient masters) are very generally appreciated by the gentler sex. On the other hand, the fondness for humbler subjects is not always referable to the homeliness of the incident represented. The subject often acquires elevation and commands respect by the evidence of mental labour and power in the artist. To a true connoisseur, this skilful application of principles derived from universal nature supersedes the mere subject; and the idea which he recognises, whatever may be its vehicle, is grand and poetical. Less experienced observers are often deceived by the title of pictures. *A Court Yard* (de Hooghe) sounds unpromising enough; but when it is seen

that the painter has represented daylight with its consequent harmony and that all is subservient to this, his aim must be acknowledged to be dignified. It is to be observed, too, that the influence of this high aim on the part of the artist often extends itself to the treatment of the materials which constitute his ostensible subject. It is easy to see from the unaffected feeling, as well as from the relative character of the execution in some (though not all) of the Dutch masters, that the real subject of their meditation was noble. I should like to see a *catalogue raisonné* on the principle to which I have alluded, distinguishing the title of a picture from the real intention of the artist. Many frequenters of the National Gallery criticise Reynolds's *Three Graces*, whence it appears they are not sufficiently aware that the personages in question are portraits of three fashionable ladies of the day, under the name of the Graces, &c. If some titles could be translated, what a contrast the real import of the work would present to the actual name. What a change, for instance, from the modesty of some of Turner's titles, *Crossing the Brook*, *Coal-barges in the Thames: Night*, to the beauty and grandeur which would require to be approached (for they ought not to be definable) in language.

With respect to the colour of the walls on which pictures are hung, opinions differ much. I am quite aware that it is necessary to consider wall, pictures, gold frames, and all, in relation to general effect; the gold, especially, is to be treated as part of the *coup d'œil*. But, though I remember examples of light walls hung with pictures producing an agreeable effect, I prefer a colour which displays the pictures more, and must also maintain that living pictures are seldom seen to the best advantage against a bright ground; the quantity of actual light (it may always be assumed) making reflected light unnecessary. My idea is, that the wall should not be so light as the lights of the pictures, and this supposes a sufficiently low tint. Of such colours the most agreeable will, I believe, be that which is calculated to give effect to the frames, either by a difference of degree or of kind—either by a deeper, richer gold colour, or by a red inclining to purple; of these, the former would look best by night. I need not recommend you to avoid too much unbroken polish in the frames, since this is now very generally disapproved of.

An Italian Villa in the Sixteenth Century.

I have hitherto, as you see, exercised, apparently without scruple, the dictatorial authority with which you have invested me. As a relief, I intended to have given you some extracts from an Italian ethical work (printed about the middle of the sixteenth century*) in which there is a chapter on the "ornamenti della casa;" but they would have been, perhaps, little suited to your purpose, and I have already far exceeded the space I ought to occupy. As I may not, however, again have an opportunity of alluding to this work, which is not unimportant in the history of Italian art, I wish briefly to advert to one or two points.

The list of pictures given seems to prove that the Italians long remained faithful to the older masters. The names of Titian and Correggio do not appear. (I hope you will not follow the catalogue in such defects.) This is not to be explained by supposing that the writer speaks for himself only; for he repeatedly says, "Some like to ornament their rooms with the works of —, others with those of —," and so on, as if professing to give a variety of tastes. I can only account for this in one way; the author lived in Milan, and it would appear that the style of Leonardo, closely allied as it was to that of the schools of Central Italy, long continued to influence the Milanese amateurs as well as the Milanese painters.

I pass over the musical instruments which, beside their chief use, "*piacciono assai all'occhio*," especially when made by Lorenzo da Pavia or Bastiano da Verona. Donatello, Michel Angelo, Alfonso Lombardi and Cristoforo Romano are the sculptors he enumerates. The terra-cottas are by Paganino da Modena; the bronzes by Verocchio and Polaiuolo. Beside antique medals, he admires those of Giovanni Corona of Venice, together with the chasings of Caradossa. Among the works of the latter, he mentions a silver inkstand in basso rilievo, "*fatica d'anni venti sei, ma certo divina*." Cameos and intaglios should be, he thinks, by the hand of Pietro Maria, Tagliacarne, &c., but above all by Giovanni di Castello.

Now for his list of painters. Filippo Lippi, Mantegna, Giovanni Bellini, Leonardo da Vinci, although, he adds, he left but few works.† Then follow the younger Lippi, and Perugino, and, heralded with appropriate honours, Raphael, accompanied by Giulio Romano. Pietro della Francesca and Melozzo da Forlì are characterised well, as indeed are all the painters. He next mentions some artists, all monks, who wrought in inlaid wood (*commesso, tarsia*), but his highest praises

* Castiglione Saba, *Ricordi ovvero Ammaestramenti*, &c. Milano, 1559.

† The author says he was an eye-witness of the Gascon cross-bowmen making a target of Leonardo's model for the equestrian statue of Francesco Sforza.

in this department are reserved for Fra Damiano da Bergamo, the artist of the choir of St. Domenico at Bologna. The engravings he speaks of are by Albert Dürer and Lucas van Leyden.

Tapestries from Flanders, carpets from Syria, Turkey and Barbary, figured leather from Spain, are all admitted to be desirable ornaments:—"Tutti questi ornamenti ancora comendo perchè arguiscono ingegno, politezza, civiltà e cortegiania." The author next describes his own treasures; but, except a head by Donatello and some rare books, he has nothing to boast of. His tastes are characteristic of the age; though a priest, his ambition is to have a collection of arms and armour, if wrought by a good Italian or German armourer; and, above all, he aspires to the possession of a large steel mirror, of the kind made by Giovanni della Barba, a German; the mirrors of glass then in use were, it appears, commonly small and imperfect. The author's judicious observations (to which I refer you) on the chief use of mirrors may reconcile you to their occasional introduction over chimneypieces, which, for the rest, are by no means the best places for pictures.

The chapter ends with a pleasing story about a mirror and a lady, and Galeazzo Visconti, Duke of Milan; a story copied by Addison (though without acknowledging the source) into the *Spectator*. The incident would not be an unworthy pendant for "Collalto,"* and might have furnished a subject for the graceful pencil of Stothard; but it is time to make an end.

THE EVOLUTION OF ORNAMENT.†

OF late years the tendency of archæological research has been to seek in Egypt and the Assyro-Babylonian area the beginnings of the early civilisations, not only of Greece, but of the bronze age generally in Europe. Indications of a reaction against a too exclusive attribution of Eastern origin are shown by M. Salomon Reinach's recent papers in *L'Anthropologie*, "Le Mirage Oriental."

But the writer presses his views to extremes as great as those he combats. Archæology is essentially a science of patience, and its problems will not yield to controversial methods. In the meantime M. Reinach's essays may stand as a useful protest against a too great haste in accepting suggestions of Eastern origins on insufficient evidence. His main thesis is that the culture represented by the Ægean civilisation is not due to Egypt or Chaldaea, though it may show contact with both, but that it is essentially Western and European. The questions raised by M. Reinach cover a very large field of archæology.

Possibly the most interesting of recent contributions to the general question is Mr. Goodyear's "Grammar of the Lotus," to which work the present paper is largely indebted.

The influence of Egypt on Greek art has long been recognised. But the close dependence of the decorative motives of Greece on those of Egypt had hardly been suspected. The proto-Doric columns of the rock-cut tombs at Beni-Hasan (twelfth dynasty) have been frequently figured. The Ionic form, though conceded to be older than the Doric, has, on the contrary, hitherto been traced to Assyria, with an ill-defined cross-reference to the floral capitals of Egypt. Mr. Goodyear has now established its direct descent from the Egyptian lotus-capitals along lines which had been foreshadowed by writers such as Reber, and with an abundance of illustration has traced step by step the modifications of the form. Further, he has shown that even the rosette, an ornament hitherto regarded as distinctively Assyrian, can be dated in Egypt, not merely as isolated examples, but in decorative use, many centuries before the earliest known example in Assyria. In short, Mr. Goodyear's book establishes the fact that Egypt played a part in the art of the ancient world similar to that of Italy of the Renaissance in the modern.

With the obscure questions of origin which lie at the back of Egyptian civilisation, and the contest for priority in the Mesopotamia region, I am not concerned. Nor is the preceding statement to be taken as implying a concurrent extension of social or political influence, or even conscious copying of Egyptian originals, but merely the extension by contact, direct or indirect, of the decorative motives of Egyptian art. Intercourse implies exchange, and in particular instances the spread of patterns may have taken place in an opposite direction to that of the more important culture and race movements. Mr. Goodyear has properly guarded himself on this point. He remarks:—"It does not weaken our estimate of the influence of Italian Renaissance civilisation upon modern Europe to know that there was not one principality in Italy after 1530, outside of Venice, which was not ruled or controlled by a foreign dynasty."

Some of the details in Mr. Goodyear's argument have

* See Rogers's *Italy*.

† From a paper on "The Origins of Prehistoric Ornament in Ireland," by Mr. George Coffey, A.I.B., M.R.I.A., published in the "Journal of the Royal Society of Antiquaries of Ireland."

been questioned. For instance, as regards the Assyrian palmetto ornament and the ivy-leaf pattern of the Greeks. But points in controversy such as these do not affect the main argument of the book, and may be left for settlement to a fuller discussion of the entire body of evidence bearing upon them, and, I am tempted to add, a more sympathetic examination of so important a work than up to this it has received. It is sufficient to say here that the essential point in the argument is not whether the Assyrians and Greeks knew certain patterns as conventional representations of palm and ivy, or not, but that the decorative types of these patterns were fixed in Egypt many centuries before they appear in other civilisations, and, consequently, that whether the floral form be consciously translated or merely imitated, the pattern is Egyptian in origin. Bearing in mind the Renaissance analogy already mentioned, the importance of a clear understanding of this point will be apparent. It is conceded that any given people might, independently, develop any given pattern. But it is asserted as a fact that, with few exceptions, this has not been the case in ancient Europe. On the contrary, widely-spread patterns, it is contended, can be shown to have had centres of origin, and to have been extended by copies, and copies of copies, modified by local tendencies. Where two forms of ornament, which can be related artistically, are found in use among different peoples, and the ornament can be dated earlier with one people than the other; and, further, where it can be shown that the peoples were in contact commercially or otherwise, it is assumed that the younger people, as regards the particular form of ornament, have borrowed from the elder. For from the fact of the ornament being earlier with the elder people, it is more than probable that it would have reached the younger by intercourse before they could have developed it independently.

Mr. Goodyear's argument is based on the discovery of a principle or law of Egyptian ornament, in accordance with which the various decorative patterns are shown to be conventionalised forms of the lotus. The adverse reception which his work received at the hands of reviewers may be accounted for by the fact that the writers probably had not made a special study of design, and were reluctant to throw over the pre-conceived idea that geometric ornament is the most primitive form of art and earlier than naturalistic representation. The specific objection which may be urged on historical grounds against Mr. Goodyear's theory of Egyptian ornament I shall take up presently. It is desirable that a brief attempt should be made to acquaint the reader with the general bearing of the question of conventionalisation in ornament before we discuss that objection.

But Mr. Goodyear no longer stands alone. While he was working out the problem for Egyptian art, Professor A. C. Haddon had independently reached similar conclusions in regard to the savage art of British New Guinea, and Mr. H. Balfour had arrived at like results in the Pitt-Rivers Museum, Oxford, working on the method of "series" originated by General Pitt-Rivers. Further, it appears that Mr. Percy E. Newberry had, in 1885, worked out the derivation of the Ionic form, including surface patterns, from the curling sepals of the lotus; but, though he had prepared his matter for press, he was unfortunately anticipated by the publication of Mr. Goodyear's papers on the same subject in the "American Journal of Archæology," in 1888.

And, as though the subject was in the air, yet another and another independent worker was in the field. As far back as 1881 Dr. Hjalmar Stolpe, of Stockholm, was developing similar views on the ornamental art of savage peoples; and in 1891 Mr. Charles H. Read published an exposition of ornamental transformation in examples from the south-east Pacific.

In America the principle of conventionalisation of realistic prototypes has been applied by Mr. William H. Holmes to the study of the ancient art of the province of Chiriqui, Columbia. At the conclusion of an important paper, published in 1888, he makes the following generalisation:—"The agencies of modification inherent in the art in its practice are such that any particular animal form extensively employed in decoration is capable of changing into or giving rise to any or all of the highly-conventional decorative devices upon which our leading ornaments, such as the meander, the scroll, the fret, the chevron and the guilloche are based."

It is remarkable that so many investigators, working apart and on different materials, should thus about the same time have reached such closely-related conclusions.

It may be stated parenthetically that the influence of the textile arts in imposing geometric conditions on ornament has probably reacted more or less strongly, according to the relative stages of development of the arts, on the decorative motives of pottery and other arts, and in some instances may have determined the line of descent of the patterns. But the numerous series of patterns conventionalised to geometric forms in examples of free carving and painted decoration, in which the descent appears to be through the principles of copies of copies or of suggestion prompted at each stage in the evolutionary series, preclude generalisation. Mr. Holmes found that

the explanation he had given of ancient Pueblo art, in which he traced the decoration to a "mechanical origin mainly in the art of basketry, and thus accounted for its highly geometric character," could not be applied to the geometric forms of Chiriquian art. He adds:—"In beginning the study of Chiriquian decorative art, I found it impossible to approach the subject advantageously from the geometric side, as was done in the Pueblo study, since life elements so thoroughly permeate every part of it." In each case the evidence must be considered with reference to the local conditions and relative priority and development of the arts.

The theory that ornamentation has been derived from naturalistic representation through a process of conventionalisation, that naturalistic art precedes geometric decoration, was at the time of the publication of "The Grammar of the Lotus" known only to a few students of the subject. The argument of the work was not therefore fully appreciated. Opportunities of frequent discussion of the subject with Professor Haddon, who was at the time working out the problem for savage art, had made me familiar with the theory before the appearance of Mr. Goodyear's book. The latter established its wide, if not general, application.

The principle, as in the case of most principles of extended application, is not so new as it looks. As far back as 1849, Sir John Evans, of whose work on this subject Mr. Goodyear does not appear to have been aware, had applied the same process of reasoning to explain the types of the Gaulish and British coinages.

The types of those coins are chiefly derived from the *stater* of Philip II., modified to some extent by other Greek types, through a series of copies modified by a tendency towards conventionalisation and symmetry. Types which appear to be wholly decorative are shown to be descended from the laurelled head of Apollo on the obverse, and the biga on the reverse of the Philippi. On the obverse we see the wreath of the original type persisting as the most prominent feature of the copies; the ear survives in the crescents, and finally all tradition of the original type is lost, and a symmetrical arrangement of the wreath feature adopted, with crescents or ears, back to back at the centre. On the reverse the recollection of the second horse is at first preserved in the duplication of the horses' legs, then the horse is further simplified, the legs disconnected from the body, and the prominence of the joints accentuated as pellets. The wheel of the chariot is set free, and may occupy any portion of the field. Finally the horse is completely disjointed, the legs surviving in dumbbell-like objects, and the round prominences of the joints give rise to an ornament of pellets in the field of the coin. Upon the general subject of the designs, Sir J. Evans writes:—

Among barbarous nations the laws which regulate the types of a coinage of this kind, consisting of successive copies of copies of a given original, are much the same as those which, according to our best naturalists, govern the succession of types in the organic kingdoms. As with plants or animals of any group or family, there are two tendencies to be traced in these successive copies—the one to retain the character of their ancestors, the other to vary from it. The main principle is, no doubt, that of "atavism," or taking the character of the parent; but another principle of more importance, as far as results are concerned—that of the perpetuation of varieties when they were in any way advantageous—is equally at work in both cases. In nature those varieties appear to have become more or less persistent which, in the "struggle for existence," have presented advantages over the present form in their relation to external conditions. But in the succession of types of these British coins, the requirements which new types had to fulfil in order to become to a certain extent persistent were, firstly, to present facility of imitation, and, secondly, symmetry of form. The natural instincts of uncivilised man seem to lead to the adoption of simple yet symmetrical forms of ornament, while in all stages of culture the saving of trouble is an object of universal desire. The reduction of a complicated and artistic design into a symmetrical figure of easy execution was the object of each successive engraver of the dies of these coins, though probably they were themselves unaware of any undue saving of trouble on their part, or the results which ensued from it.

Briefly summarised, the argument of "The Grammar of the Lotus" may be stated thus. Working on similar lines to Evans Mr. Goodyear derives the leading decorative motives of the Egyptian patterns from certain spiral and other modifications of lotus ornament. He then traces the influence of Egyptian patterns in the decoration of the earlier civilisations of the Mediterranean, and finally extends that influence to the pre-historic art of Europe generally. With regard to the latter portion of the subject the argument is rather suggested than developed in detail, and examples of western geometric ornament, with which we are immediately concerned, are not considered.

To return now to the historical objection. The weak point in the construction of Mr. Goodyear's theory is this. The development of Egyptian patterns does not appear to be proved historically. It is the fashion to decry "The Grammar of the Lotus," and adverse criticism can press this objection with apparent effect. The impression is left on the reader's mind

that examples are selected from widely separated periods and then arranged in series irrespective of date, and the development and modification of the patterns argued from the artistic relations of the series, regardless of historical sequence. Thus the spiral is fully developed and worked with great beauty of treatment on the scarabs of the twelfth dynasty, but the weight of evidence of the interdependent association of spiral and lotus, to which the origin and development of the spiral and spiral patterns appear to be traced, lies in the eighteenth to the nineteenth dynasties. I am not sure that on a strict reading of the text Mr. Goodyear has left himself open to the above objection. As regards the twelfth dynasty spirals, he has adduced examples from the scarabs of associated lotus, and referring to a developed spiral pattern from Beni-Hasan, unfortunately destroyed, he fairly observes that the demonstration from a later pattern, which he relies on to prove lotus details, "reacts on the original Egyptian forms, whose history is now obscure and whose earliest evolution is unknown." It may be further urged that the existence of even a single example of developed spiral pattern of the ceiling order in the twelfth dynasty implies a whole series of patterns in that dynasty now destroyed or still to be recovered. But the spiral is carried back by the scarabs to the fifth dynasty, and it may be contended that its derivation from the lotus is not proved.

A point in favour of Mr. Goodyear's view is the representative character which he claims for the spiral as a symbol for the lotus. Evidence is accumulating as to the religious and magic use of ornament by savage peoples, which may ultimately have an important bearing on the development and use of ornament, but the subject is at present too obscure and would take us too far to discuss here. In any case the representative character of the spiral if established would be equally well explained as the survival of an incorporated spiral motive. Looking at the series of scarabs of the fifth to the twelfth dynasties, published by Professor Flinders Petrie in "Historical Scarabs," on many of which spiral patterns are found, but not incorporated with the lotus till the twelfth dynasty, it is apparent that the weight of evidence of the scarabs is against the lotus origin of the spiral. The preceding remarks apply equally to the lozenge patterns. This may well seem a fatal objection to the theory of the descent of Egyptian geometric ornament and derived patterns from conventionalised lotus forms.

But a wider view of the subject will enable us to see that this need not be so. The origin of geometric patterns through the conventionalisation of naturalistic prototypes is a larger subject than Egyptian ornament, of which the latter is but a particular case. Evidence has now been collected over a large area of savage art, which leads us to believe that geometric patterns, with perhaps the exception of some zigzag, chevron and triangle ornaments, the history of which cannot always be traced, have been invariably derived from naturalistic forms. In many instances the whole series of the transformation is found on a single object. In such cases the series has probably been determined by the limitations of position of the several parts. Dr. Stolpe writes in reference to Polynesian ornament:—"Nor were the transformations due to any want of skill on the part of the Herveyan carver, because he often used to place on the very same implements the realistic prototype, as well as the whole series of intermediate forms, down to those that are most transfigured; and this fact furnishes proof that the artificer must have been thoroughly conscious of the meaning of even the most 'degraded' design." And dissenting from Mr. Read's view that "the artist would unconsciously lean towards a kind of generalisation of details which, by saving his time, would enable him to produce more, and naturally at a cheaper rate," he adds:—"No doubt there were other reasons for conventionalising, and one of the most substantial, I think, was that the higher standing types were not suitable decorations for every part of the objects adorned. On the 'paddles' we therefore see them almost exclusively confined to the flat rectangular terminals of the shaft. If this space did not allow more than one row of complete figures, what remained was filled up with rudiments of them. On the shaft the space was usually still more scanty, and on the blades the very shape of them made the most conventionalised stages to be the fittest adornment."

Evidence of historical sequence is not forthcoming for savage art, except in so far as new forms have been introduced by foreign civilisation. Dr. Stolpe asserts "no chronological signification exists at all in the history of these developments. On the material known to us, phases the most remote from each other in order of development occur even on one and the same implement. To distinguish between earlier and later objects, one has no other guide than an appeal to the workmanship which here, as elsewhere in the world, deteriorates in proportion as foreign civilisation gains ground."

But in the examples of Polynesian ornament discussed by Dr. Stolpe, we find not only that the complete series of transformations is represented on one and the same object, but that somewhat of a religious significance is attached to the ornament; and the classes of objects decorated with conven-

tionalised ornament, even when the realistic prototypes are absent, furnish a convincing line of evidence as to the descent of the patterns.

Moreover, Professor Haddon found that in British New Guinea, among neighbouring peoples, the tendency to conventionalise had, in some instances, followed different paths, probably due to some selection of feature of the realistic prototype, or some idiosyncrasy or preference of fashion in the particular tribe—in one case leading to curved lines, concentric circles and spirals, in another to straight lines and angular ornament. Here, again, the argument based on the existence of several distinct lines of descent of patterns, not merely distinct at certain stages, but separable along the whole line of each series, and the specialised use of the patterns, is very convincing as to the origin from realistic prototypes of the geometric ornament of British New Guinea.

But if we put aside prepossessions acquired from the study of the higher developments of art, the fact that realistic representation is prior to geometric ornament should not surprise us. If we watch a child drawing, we find that geometric form, or ornament of any kind, is not present to the child's mind. On the contrary, its pleasure is centred in realistic representations of objects which have aroused its interest—animals, boats, trains, &c. And so with primitive man, he draws in the earlier stages realistic representations of the things that interest him. It is worthy of note that representations of the sun and moon are rare in primitive art; the subjects depicted are taken, for the most part, from the life immediately in contact with man, in which his daily needs are centred. Pictorial representation in this stage can, indeed, hardly be called art; its end is visualised realism.

Ornament represents a higher stage in intellectual development; it means adaptation, arrangement and relation of lines, symmetry and co-ordination of parts. In fact, geometric patterns represent a very considerable intellectual advance as compared with merely imitative drawing. A higher stage is entered on when naturalistic representation is developed under the conditioning limitations of art—when, in short, the subject is "treated" and not merely imitated.

The bearing of this lengthened digression on the chronological difficulty in Egyptian art is this. It does not appear to me to be proved that the spiral has been derived from the lotus. But Egyptian art, as we know it, has no beginnings. It is reasonable to assume that the geometric stages were passed through in a period preceding Egyptian ornament, which is at present a blank to us: that the civilisation from which that of Egypt must have at some time emerged was already in possession of the spiral and other geometric forms. But conventionalisation in ornament is a principle which has continuously operated in all stages of art, and the prior existence of geometric forms would serve as the cutting of the channel, or an attraction towards which Egyptian ornament would conventionalise. A passage in Dr. Stolpe's essay explains my meaning:—"An ornament may have more than one source. It often happens that when a series of developments approaches a certain well-known geometric motive, it quite simply incorporates the latter by reason of this relation. After such an incorporation has taken place, it will be difficult enough to decide to which of the two divisions an ornament properly belongs." Thus though the spiral may be found in the earliest examples of Egyptian ornament, still the series of transformations through which the lotus is shown to be conventionalised to spiral forms, and finally to be replaced by spiral patterns, is a true series. The fact that the spiral cannot be proved to have necessarily originated in the curling over of the sepals of the lotus, does not impair the evidence of the series of the "Ionic" forms through which derivation of the Ionic spiral capitals is traced to the conventionalised lotus.

As regards the secondary portion of Mr. Goodyear's work, in which he is dealing not with cases of direct descent, but of copies, and copies of copies of Egyptian originals, the argument of conventionalisation is absolutely untouched by the historical objection, and rests on the positive evidence of each particular series, in accordance with the principles laid down by Sir John Evans for the types of the Gaulish and British coinages, to be accepted or not in proportion as the steps in the transformations can be satisfactorily made out, and the lines of intercourse along which the patterns have travelled established.

THE SOANE MUSEUM.

THE *Globe* has the following chat between the new curator and a correspondent:—

"I don't intend to vegetate here," remarked Mr. G. H. Birch, F.S.A., the well-known architect. He was seated in that quaintly arranged and comfortably furnished room which the late Sir John Soane used as a breakfast-room, and in which some of his choicest relics are stored. There was the ruddy glow of health upon his cheek, for Mr. Birch is in the prime of life, and his remark was in reply to a suggestion of strangeness

that he should settle down so early in life to a quiet old age as a curator even of so curious and fascinating a collection as that in Lincoln's Inn Fields. A curatorship of this class is generally regarded as a sort of pension, but Mr. Birch declared that he declined to accept it in any such spirit. "I am going to make it of interest to every one," and he proceeded to show how he should do so.

First, it must be remarked how few people know much of the Soane Museum. To the majority it is a strangely built house, overcrowded with curios of the description usually found in private collections. To the few it is known to be full of special features that can be found nowhere else, a collection worthy of the closest study. But it is improbable that any living person knows thoroughly what the place contains. Though its former curators have been men of culture, and of much enthusiasm with regard to the relics placed under their charge, it is doubtful whether even they have ever made themselves thoroughly acquainted with the contents of the place. And this, not because of any want of diligence on their part. The fact is that Sir John Soane had a sort of mania for two things. One was the use of looking-glass in every possible corner and in the most unexpected places, and the second was for making cupboards, folding doors for pictures, and hiding-places on a sort of secret panel arrangement of his own. The former gives the place a weird aspect. "It is a good thing I am not a nervous man," Mr. Birch said; "but I must confess when I came here I was often startled by seeing my own reflection—which in the dusk I did not recognise—advancing towards me from out of odd nooks and crevices. At times the effect was ghostly, but I am getting used to it." By the second feature of the place, Sir John Soane made the house hold three or four times its apparent capacity, and things are so crowded together that constant discoveries are being made of articles of the greatest possible interest. There are few men, if any at all, possessing such a knowledge of everything valuable that they would be capable of appreciating the worth of all the treasures. To do so a man would have to be a bibliophile, an art connoisseur, an architect, a draughtsman, an Egyptologist and an archaeologist, not to mention other less important qualifications, for such a wide range of curiosities and specimens—covering as it does every art and almost every science—has probably never before been collected under one roof. That is why many valuable things are hidden away unappreciated.

There are many secret places that have rarely been opened, many nests of drawers of which the keys have been lost, cupboards that may simply have skeletons in them. To open these hidden stores of wealth, to make fresh discoveries, and to make them available to the public is one of Mr. Birch's ideas. He has not been there long, but he has already made one discovery on which he prides himself. Taking a small key from his pocket, he crossed over to the other side of the fire-place, to where the wall was panelled with wood. There seemed no hiding-place there, and no room for one, but, inserting the key in a concealed keyhole, he opened a narrow doorway, through which he could just pass. Beyond was a "strong room," and from this he returned with a paper-covered book, that looked as though it might have been a copy-book of a child of Brobdingnag. It was, however, a book in which were designs of buildings erected by Vanbrugh, an original account-book of Blenheim Palace, and original drawings by Thorpe, an architect of the reign of James I.—a perfect mine of interest to architects. With reverential care Mr. Birch displayed its contents, and then gathered up his treasure and carried it carefully back to its hiding-place. Other panels he opened in this room, other unsuspected bookcases he revealed, full of old books, many of which doubtless are of considerable value, but which the casual visitor does not deign to notice.

And in respect to cupboards, it must not be forgotten that in his will Sir John specified two, which were found carefully locked, one of which was not to be opened until fifty years after his death, and the other of which was to remain closed for seventy-five years. As Sir John died in 1837, the first cupboard has been opened. The result, Mr. Birch remarked, has never been made public; but as a matter of fact, the cupboard was found nearly empty. The most interesting thing found was a letter to Turner enclosing a cheque for 500*l.* which had never been posted. The letter—and it possesses interest from the fact that it has never before been published, was as follows:—"Dear Turner,—I saw that drawing last night and admired it very much. And if you think the accompanying cheque in any way represents the value of it, pray let me have the picture.—Yours, &c., John Soane." Whether the other cupboard will reveal anything of greater value remains to be seen.

A walk round the museum showed that Mr. Birch was wonderfully well informed as to its contents, as well as well versed in its intricate geography. In the dining-room and library he pointed to the capacious and crowded bookshelves on the walls, in the projecting piers dividing the rooms, and in the window recesses, where one usually finds shutters, and announced his determination of exploring these shelves

and examining each book—a truly Herculean task, which will certainly tax his patience and perseverance. This is perhaps one of the best known parts of the museum, and there is no necessity to linger over the pictures which cover the vermilion-painted walls, the curios with which it is filled, and the strange furniture crumbling to pieces with old age. In every other part of the museum he indicated cabinets and places to be explored, while in the oddest possible spots he showed how the space had been made the most of. Nowhere, of course, is this more noticeable than in the picture-room, which has the unique series of movable planes, shown to every visitor, which makes a room 13 feet by 12 feet equal in picture-hanging space to a gallery 45 feet long by 20 feet broad. But this is by no means the only instance, and visitors who have the time and inclination may find many others.

The pictures by Hogarth, *The Election* and *The Rake's Progress*, everyone knows; and it is noticeable how much better preserved these are here than those in the National Gallery. The Canalettos also are to everyone's taste, but there is one particular feature of the art portion of the museum which no doubt strikes some visitors. It is that one sees here pictures by artists long since dead and forgotten and whose works are never seen elsewhere. It is evident that Sir John was an art critic of the broadest possible views, and that, added to the catholicity of his taste, was a desire to perpetuate the worth of many neglected men. Who now remembers George Jones, Danby, Owen, Jackson, Howard or Bird? Yet here are pictures by each and all of them, which anyone who has patience to find them out will view with admiration. The ordinary visitor when he has gazed at the Turners, the Lawrences, the Ruysdaels, Raphaels, Reynolds, Rubens, Tintoretto, the Zuccharellis and the Watteaus, has little disposition to linger over the mass of paintings and drawings of peculiarly architectural merit, and gives but a passing glance of astonishment at the numerous designs of buildings which Sir John Soane proposed to build in various parts of London. One of these, his great design for a royal palace in the Green Park, might have been utilised had George IV. lived; but after his death more economical notions prevailed. Buckingham Palace became a Royal residence, and was subsequently enlarged by the Prince Consort. There is something pathetic in these long rows of grand edifices which Sir John found time to draw—the Royal palaces, the design for a new House of Lords, the new Houses of Parliament and Courts of Judicature, a triumphal bridge and churches innumerable, which never got further than a paper existence, and which are now but a monument to the untiring industry of the man.

Walking through the corridors, the students' rooms, the monk's parlour, the catacombs, the sepulchral chamber and the crypt, Mr. Birch showed that he is full of schemes for popularising the museum and making it of greater use. At present the prominent features of the place only are known, and those not so widely as they should be. What is wanted is that some knowledge of its hidden treasures should be spread abroad. The museum is now more readily accessible to the public than it used to be. Formerly it was only opened on two days in the week. Now, from March to August inclusive, it is open to the public four days in the week, the other days being reserved for students, of whom there is an increasing number.

SHEFFIELD SOCIETY OF ARCHITECTS.

THE ordinary meeting of members was held at the School of Art, the president, Mr. E. M. Gibbs, in the chair. Mr. Henry Longden, of London, gave a lecture on "The Working of Wrought-iron from a Practical Point of View," which was illustrated by specimens both of finished work, and of forged ironwork in process of manufacture. He first dealt with the qualities of wrought-iron, as, for example, its strength, lightness and comparative cheapness. The process of forming the parts of iron railings and gates, and of forming scrolls, twists and leaves, hammered work of iron, were then dwelt upon. Some old examples of the use of iron railings were referred to, and suggestions were made as to the best effect to be got in the designing of railings. The lecturer showed some examples of carving in wrought-iron, a difficult art, and one which, he said, should only be employed sparingly. Specimens studied from old Venetian work and of modern work now in process of execution were shown. The works of Mr. Sedding, the architect, were referred to, and it was named that some of his work, executed in Sheffield, may be seen in St. Matthew's Church in this city. Some general remarks as to the present larger use of wrought-iron work were made, and it was urged on the meeting that only work of a fine, workmanlike and characteristic order of design and execution should be used. A cordial vote of thanks was passed to the lecturer, on the motion of Mr. Hadfield, seconded by Mr. Smith, supported by Mr. Hoyles, Mr. Winder, Mr. Fenton and Mr. Gibbs.

GLASGOW ARCHITECTURAL ASSOCIATION.

THE general monthly meeting was held in the Rooms, 114 West Campbell Street, the president, Mr. A. N. Paterson, in the chair, when Mr. Wm. J. Blaine read a paper on the "History of Monumental Buildings." Dealing with the origin of these buildings in the pyramids of Egypt, he traced the development of the square tomb through Assyria to Greece, and described the sepulchre of Mausolus at Halicarnassus. He followed the round tomb from the tumuli of Asia Minor through Etruria to Rome, and showed cause for the decay of this form in the introduction of Christianity in the seventh century, which discouraged the idea of the secular tomb. During Mediæval times the tomb was part of and was absorbed in the cathedral, and it was not till after the Reformation that, owing to the revival of interest in Classic art, this class of building came again into favour. After acknowledging the pre-eminence of French architects in the design of national trophies, the lecturer proceeded to describe the national monuments of Germany, pointing out the lessons that were to be derived from that country in the patriotic grandeur of their public monuments. The folly of crowding our churches with incongruous statuary was out of all taste, and Mr. Blaine advocated the erection of both national and municipal monumental buildings for the reception of the statues of our great men. Our larger cities could well afford to acquaint their citizens in this way with a sense of their own greatness and of the devotion, courage and intelligence which had gone to build up their name.

BONDAGE OF CHARTERS.

AT a time when the Royal Scottish Academy and the Society of Scottish Artists are disputing before the Privy Council the clauses of a supplementary charter promoted by the former body, it is hardly judicious, writes a correspondent of the *Glasgow Herald*, to express an opinion either on one side or another; but it may be considered an opportune moment to recapitulate briefly the history of the charters of the Academy. In 1838 the Academy became a chartered body, and the charter, like any other new suit, fitted it for a long period; but a time came, as it invariably does, when, owing to the growth of art and corresponding increase of artists, the Academicians made the discovery that the charter required to be altered. Complaints were rife about the exclusiveness of the members of the Academy in regard to their exhibitions, and to meet the views of the younger artists the Society of Scottish Artists was formed. This had the effect of making the Academy move a little faster, and at last, in 1891, the new charter, the outcome of much discussion within and without the Academy, became law. One of the clauses of this new authority provided for transforming the associateship of the R.S.A., which up till this time had been limited, into an unlimited order. At the first election under the new charter a large number of associates were elected, and in the following year the same thing occurred. This, although the result of their own vote, offended some of the Academicians, and the president, Sir George Reid, resigned his position. *Pourparlers* followed between the Council and Sir George, and eventually the head of the Academy agreed, on certain alterations being made on the charter, to withdraw his resignation. These conditions were debated and modified, and ultimately took shape in the supplementary charter which is now before the Privy Council.

Such in brief is the history of the charters of the Academy, and the moral to be drawn is the obvious one, that it is better for an art society to have a simple constitution and rules than to be governed by the more rigid system of charter law. The difference between the two is—with a charter, alterations can only be made by applying to the Privy Council, a method entailing great expense and the usual red-tape waste of time; without it the members themselves have the power to alter their rules quickly and without cost to suit the times they live in. The troubles that afflict and have afflicted the Royal Scottish Academy are undoubtedly caused by its being a chartered body. Had there been no charter it is evident that rules could have been altered to suit circumstances, and as one result there would not have been any Society of Scottish Artists at the present day. It took several years to prepare and obtain sanction for the charter of 1891. Probably it was intended to last as long as the first one, but no sooner was it in working order than it required to be altered. Doubtless the same thing will occur again and again. In this matter of charters the Royal Scottish Academy has followed in the footsteps of the premier body, the Royal Academy of Arts, the laws and regulations being almost identical. The "bondage of charters" has not been felt so much in the ranks of the older Society, its strength and position enabling it to stand repeated assaults with immunity, but if the Royal Academy has not required to alter its charter, the members have either acquired a contempt for it or have gained courage to ignore it. One of the clauses of the charter of the Royal

Academy expressly forbids its members from being connected with any other Society of artists "established in London," and yet, as everyone is aware, Sir John Gilbert, Alma-Tadema, Professor Herkomer and many other R.A.'s belong to art societies whose headquarters are in the great Metropolis. Two well-known art associations, the Royal Society of Painters in Water-Colours and the Royal Institute, have shown wisdom in refusing to have charters. They are contented with a constitution and rules, and thus each enjoys the prestige and privileges of a Royal Society without any of the drawbacks that a charter entails. In Scotland the Royal Scottish Society of Painters in Water-Colours furnishes another example. Last year it was found that some of its rules were getting rather antiquated. These were no sooner discovered than they were remedied. With very little expense and with no long delay the change was made. It is evident that when charter and constitution are placed against one another the latter has everything in its favour. Simplicity and freedom are its characteristics. For the charter it can only be said that it prevents any other society taking the same name as the one in possession. There are, of course, charters and charters, but so far as art societies are concerned a charter is like an iron shackle, difficult to remove; whereas a constitution may be compared to a leathern thong, which can be unbuckled or tightened at will.

THE TOWER BRIDGE.

THE Bridge House Estates Committee of the Corporation have presented a report on an application by Mr. J. Wolfe Barry, C.B., for some additional remuneration in connection with his services as engineer of the Tower Bridge, the original estimated cost of the bridge having been considerably exceeded by reason of extra works, necessitating a longer period of time in its construction beyond that first contemplated, and consequently throwing upon Mr. Barry much additional expense for assistant engineers, superintendents, clerks of the works and others. The amount which Mr. Barry considered he was strictly entitled to for extra service and money out of pocket was 16,650*l.*; but, after friendly negotiations, the committee recommended the Court to pay him 12,000*l.* in full satisfaction of all claims. Mr. Barry had also consented to act as consulting engineer in respect of the bridge for three years without any payment. The whole of the works had been most successfully carried out, and the bridge itself was not only a masterpiece of engineering skill and the largest ever erected on the bascule principle, but was also an ornament to the Port of London, and the greatest credit was due to Sir H. Jones and Mr. Barry for the design of the bridge, and to the latter for the way in which it had been carried out. From the opening of the bridge till now no hitch had occurred in the raising or lowering of the enormous leaves (weighing 1,000 tons each), and so easily had the machinery worked that no block had occurred in the traffic. The traffic on London Bridge had been satisfactorily relieved, and the bridge was a benefit to the whole Metropolis.

YORK ARCHITECTURAL SOCIETY.

MR. H. PERKIN, F.R.I.B.A., presided on Saturday evening at the annual dinner of this Society, and Mr. G. B. Bulmer, F.R.I.B.A., of Leeds, responded for the Society of which he is a fellow and kindred societies. In his address the President remarked that as to the repairs that were constantly needed to the exterior of the Minster, it would appear from the decay into which it was falling that the funds were quite inadequate for efficient renovation. He asked if it was not competent for that Society to make a representation to the Dean and Chapter, suggesting that they should make a supreme effort to obtain the necessary sums required for the next twenty years or so. If a further appeal were made, some large-hearted Churchman would respond with substantial help, as in the recent case of Peterborough Cathedral. Mr. Perkin was re-elected president.

SCHOOL BUILDINGS.

Slaithwaite and Lingards U.D. School Board.—The first new Board school erected by this Board was opened on Monday morning last, January 7. The school is situate at Wilber Lee, about one mile from Slaithwaite. It contains one large main room, two classrooms, infants' room, separate cloak-rooms, lavatories and entrances for boys and girls, and provides accommodation for 178 children. The rooms are fitted up with dual desks. Adjoining the school the Board has built a residence for the schoolmaster. The building is built of local stone and the roof is covered with green Westmorland slates. The internal woodwork is of pitch pine varnished. The total cost, including furniture, will be 2,300*l.* Mr. J. Berry, of

9 Queen Street, Huddersfield, has been the architect. At the monthly meeting of the Board, held on Thursday last, Mr. Berry was instructed to prepare plans for a second mixed school proposed to be built at Nields, Slaithwaite, to accommodate 300 scholars.

The Adornment of St. Paul's.

SIR,—Perhaps you will allow me to make one or two remarks on the "Note" which appeared in last week's issue of *The Architect*.

I may say that no jealous feeling prompted my criticism of what has been done, and if I can stir up some enthusiasm amongst artists and architects for the glorious work which we are discussing, if the lamentable apathy which seems to hang over every national work can be thrown aside, some public good and some help to the funds must result.

You will, I know, allow me to explain that the words you quote, "there has been a most unfortunate waste of money, and, as regards the progress of English art, the result is degrading," did not apply particularly to the work done by Mr. Richmond, but to the expenditure during the last quarter of a century of the 56,000*l.*

I have no desire whatever to exclude "ecclesiastical" designs—indeed, my reference to St. Annunziata at Genoa shows this—and I should be the first to support your view that we should have "sermons in stones"; but sermons in stones or in words are of very little use, however eloquent, however beautiful, unless the eyes or the ears are able to distinguish what is done or said. That is the burden of my song, and I shall hope fervently to shortly be able to see Mr. Richmond's work, or some other artist's work, which is thoroughly fervid and religious in feeling, beautiful in design and execution, and "to be understood of the people."—Yours obediently.

WM. WOODWARD.

13 Southampton Street, Strand: Jan. 8, 1894.

GENERAL.

Mr. J. Holden, architect, Manchester, will give an address on "Ancient Lights" at the next meeting of the Sheffield Society of Architects.

Sir Leader Williams, the chief engineer of the Manchester Ship Canal, is about to relinquish that position, as the canal is now complete. He will be appointed consulting engineer.

Plans for a new Roman Catholic church for Morecambe, prepared by Messrs. Pugin & Pugin, architects, have been approved by the Morecambe Urban Council.

Mr. Hubert Hall, F.S.A., has been appointed honorary secretary of the Royal Historical Society, in succession to the late Mr. Patrick Edward Dove.

The Liverpool Architectural Society will hold an open-meeting on Monday, the 14th inst., when members are invited to introduce subjects for short discussion.

Mr. Thomas Hunter, W.S., of the firm Macandrew, Wright & Murray, W.S., has been elected town clerk of Edinburgh.

The Annual Conversazione in connection with the Birmingham and Midland Institute will be held next week.

The Queen has consented to be the patron of a bazaar, to be held at St. Martin's Town Hall in May next, for the building fund of the Royal Westminster Ophthalmic Hospital, and the Princess Henry of Battenberg has promised to open it on May 14.

The Annual General Meeting of the Royal Meteorological Society will be held, by permission of the Council of the Institution of Civil Engineers, at 25 Great George Street, Westminster, on Wednesday, the 16th inst., when the report of the Council will be read and the election of officers and Council for the ensuing year will take place.

Mr. Henry Nash, head of the firm of Henry Nash & Co., metal merchants, Liverpool, was found dead in his chair on Tuesday afternoon at his office. He had come to business in apparently good health.

Mr. P. Drew, architect, was on Tuesday re-elected president of the Royal Society of Antiquaries of Ireland, for a term of three years.

The Exhibition of Drawings by Sir E. Burne-Jones at the Whitworth Institute, Manchester, was closed on Saturday. About 40,000 people had visited the gallery.

The Architect.

THE WEEK.

THE employment of amateur architects is not an economical proceeding. To that well-known yet neglected truism Mr. JOHNSTONE, of Lochwinnoch, can sadly testify. He resolved to erect a cabinet factory, and decided to dispense with an architect and a building inspector. His traveller, with that presumption which is the most prominent and enduring characteristic of "bagmen" from time immemorial, prepared the plans. The factory would probably have remained as a monument of commercial enterprise if it could have been preserved under a glass case, for any structure of the kind would have been stronger than the building. But the gale of December 22 quickly brought the factory to an end. Four men were killed and fourteen injured. It was necessary, therefore, to hold an inquiry. One of the witnesses was Mr. T. G. ABERCROMBIE, architect, Paisley, who had made an official inspection of the building. He said the walls were carried too high for safety, and sooner or later the vibration would have caused a disaster. The glass used was too slight, and the iron ties were not strong enough. It was recommended that what remained of the factory should be removed; but under the circumstances they must be foolhardy men who will undertake that work unless costly precautions are carried out. It is said the loss amounts to 4,000*l.*, but of course the amount which will have to be paid for compensation will amount to a much larger sum.

THE Tribunal of Appeal provided for in the London Building Act is now formed. It was enacted that one member should be appointed by a Secretary of State, one by the Council of the Institute of Architects, and one by the Council of the Surveyors' Institution. The nominees respectively are Mr. D. CUBITT NICHOLS, Mr. ARTHUR CATES and Mr. T. CHATFIELD CLARKE. They are appointed for a term of five years, and are eligible for reappointment. The remuneration is to be either by way of annual salary or fees, or partly in one way and partly in the other, as a Secretary of State may fix. The appointments will not excite surprise, and they were anticipated by many architects. The three gentlemen have had ample experience in London, and it is not likely that any of them will give occasion for the enforcement of the clause which makes it lawful for the Lord Chancellor to remove any member of the Tribunal for inability or misbehaviour.

IT is proposed to erect a Swiss village of a comprehensive character in connection with the exhibition of next year which is to be held in Geneva. The outlay will at least amount to 12,000*l.* There will be twenty-two cottages, corresponding with the several cantons, and each of them will represent the most picturesque local type. The interest of the buildings will be unquestionable. In each cottage some local industry will be carried on, such as carving, clock-making, weaving, embroidery, &c., and the occupations of the people in their homes will become more evident from visits to the exhibition than from any descriptions, or treatises on political economy, or books on Switzerland.

IN the speech which was delivered by the secretary of the Education Department on Friday last, one of the causes of defective teaching in this country was pointed out. Addressing the principals and lecturers of the training college, Sir GEORGE KEKEWICH said that, while the buildings of some training colleges were suitable, there were others which were years behind the times. There were buildings that were meant to serve the comparatively humble purposes and aims of educationists in days long past, and which, without alteration, were being used to provide teachers for a system of education that was based on advanced principles. There was a marked contrast between some of these buildings and the modern elementary schools, and that contrast was so much to the disadvantage of the former that it could not fail to attract public notice and criticism. To put these colleges on a perfect footing would require a

considerable sum of money and a large degree of energy, but public opinion was strong as to the necessity of maintaining in all respects the efficiency of our training colleges in a manner fully suited to the requirements of the time. Sir GEORGE KEKEWICH might have added that education in schools nowadays corresponds more or less with the character of the building. The architect, as it were, forms the grooves which masters and pupils have to follow. Ill-arranged, dark and uncomfortable classrooms produce ill effects on teachers in training, and when they enter on their duties in schools they are incompetent to take advantage of the facilities which are provided for their use. In ancient days when scholasticism was supreme a teacher could set up his school under a tree in a forest, but education is now more than an exercise of memory and word-splitting: it has to do with method, which cannot be better exemplified than by the skilful planning of a building.

THE first annual meeting of the Manchester and Salford Building Trades' Association was held on Wednesday. The report stated that notification of the formation of the Association was sent to the Manchester Society of Architects, with a request that in future any communications to any of the trades represented in the Association should be addressed to it, and not to individual societies. A correspondence has already taken place between the Association and the Society of Architects on the subject of deposit of priced quantities, but no decision has yet been arrived at. Notices of a proposed alteration of working rules have been received from several of the operatives' associations, and will be dealt with in due course. The Association has very important functions to perform, and may be of great advantage to the trade in the future.

AT the dinner which was given to M. PUVIS DE CHAVANNES this week in Paris, to celebrate his attainment of his seventieth year, he described his theory of decoration in a few words. He said he was dissatisfied with the grandiose but heavy decorations which were to be seen at Versailles and in other public buildings, and he resolved to adopt the opposite extreme. Instead of painting pictures that would appear to overweight the walls, he endeavoured to make the walls appear more prominent. His figures professed to be no more than simply decorative. We have more than once explained the artist's theory at length, and have published illustrations from the more successful of his paintings. M. PUVIS DE CHAVANNES holds an unique position among decorators, but it is a remarkable fact that, in spite of the size and originality of his works, he has not obtained a tithe of the rewards which men of inferior powers have secured. He has gained, however, the esteem of all artists from his fidelity to his convictions. For eight years' labour and materials he obtained from the State a sum of about 2,000*l.*, and his average income probably does not exceed 400*l.* a year. It is no wonder M. PUVIS DE CHAVANNES possessed only a modest studio that contrasts strangely with those of younger and more fashionable painters. He is not, however, the only great artist in Paris who is not one of Fortune's favourites.

THE condition of that beautiful church, the Trinité, in Paris, is again exciting apprehension. From time to time fragments of the masonry are loosened, and, as there is a public garden in front of the church, which is generally occupied, the fall of a stone near one of the benches or walks would be likely to cause an accident. M. BALLU'S building is hardly thirty years old, and the scaling of the stone does not necessarily mean the instability of the church. It is curious, however, that the sculpture of the exterior is also succumbing. The public can more easily see the effect of the weather on figures than on masonry, and it is excusable if they conclude that the building is tottering because an arm or a part of a robe has disappeared. The congregation is wealthy, and it would not cost much to bring the front of the building into a condition that would allay all fears about its safety; but the Municipal Council have charge of the conservation of the building, and do not appear disposed to lay out money on it, or to allow private individuals that privilege.

THE OLD MASTERS EXHIBITION.

SEVERAL years have gone by since the Academicians were as lucky in negotiating for paintings of equal merit with those which can now be seen in Burlington House. They are, it is true, brought together without any regard for principle or system, and as usual the exhibition fails from the want of a dominant idea. But that objection would be no less applicable to the summer exhibition, which does not exemplify the varieties of modern English art. We feel, in looking at the walls, that accident rather than design has determined the character of the collection. But the pictures are interesting, and students and the public will be wise to study them while they have the opportunity.

The first room is mainly occupied with the works of Englishmen, but Scotland is represented by JOHN PHILLIP and RAE BURN, and Ireland by Sir M. A. SHEE. If we follow the order of the catalogue, PHILLIP comes first with his *Selling Relics, Cathedral Porch, Seville*. As it is incomplete, it is hardly a subject for criticism. The painter was deficient in imagination, and he was not strong in composition. He was compelled to depict everyday scenes. In this case, as in many others, he selected an incident which, from its lack of interest, would not be suited for a drawing in an illustrated journal. REYNOLDS'S *Tribute Money* is a small canvas, and almost a monochrome. It aims at an almost Rembrandtish effect. There are several portraits by the first of the Presidents in the room. *Sir William Fawcett* is one of the Lord HEATHFIELD type of soldiers. The contrast between the scarlet coat and broad crimson sash must be less effective than formerly. The *Marquis of Granby* might have hung before Mrs. TONY WELLER's hostelry at Dorking, for the colours have faded, but fortunately the expression of character is still perceptible. The *Dead Bird* is a delightful figure of a little girl, but the cause of all her woe has to be taken on trust, for no bird is visible. The *Miss Kitty Fisher* excels all the portraits in the room, on account of the beauty of the lines and the apparent unconsciousness of the courtesan who so innocently fondles doves. The face has that "expression virginale, enfantine même," which, according to M. DUMAS, was one of the characteristics of La Dame aux Camélias.

The third president, Sir T. LAWRENCE, is represented by his *Master Lambton*, who is posed, as everybody knows from the engravings, as an infantile BYRON, seated in a most uncomfortable position on what is supposed to be a rock. Probably he was a harmless child, but he is made to appear as the type of youthful priggishness, and his crimson dress looks as stiff as if it were made of red morocco leather. *Miss Croker*, by the same artist, has eyes in a fine frenzy rolling, but she is made to hold an eye-glass in order to aid them. Another president, Sir M. A. SHEE, displays a second boy meditating on the mystery of the world, and, like his fellow philosopher on the opposite wall, he also wears a red dress. Sir HENRY RAE BURN also shows boys in red, and the young MACDONALDS of Clanranald are so boyish it is a pleasure to glance at them, but only a parent or a clansman could endure the constant sight of all their snapping fingers. One of the wonders of our time is the resurrection of so many ROMNEYS, and they are still appearing. Lady HAMILTON appears in her usual white dress, and she wears a bonnet and reads a newspaper. The *Miss Kitty Calvert* was likely to have been produced on economical terms, for ROMNEY was never more careless in his hands and arms. His *Mrs. Inchbald* is a kindly, quiet, elderly lady, with apparently little of the stage about her. This is one of the most interesting of the artist's portraits. WILLIAM DOBSON'S works are a welcome sight. His *Inigo Jones* is preferable, as suggesting genius, to VANDYKE'S portrait; and the *Portrait of a Man*, who appears in a buff coat and cuirass, would pass for an ideal officer of the Parliamentary army. The single portrait by GAINSBOROUGH in the room is *Miss Willoughby*, a rather inane subject, and the artist seems to have been more hasty than usual in completing it.

CONSTABLE'S *Salisbury Cathedral and Deedham Vale* and *Scene on River Stour* are in his usual prolific style, with as much suggestion of detail as a pre-Raphaelite drawing. They would assert their power in any gallery. But for many there is more attraction in the delightful *West End Fields*,

Hampstead, which might be considered as a novel production of the master. The contrast between the light green of the meadow in front with the few dark green trees in the middle distance, by which an immense expanse is suggested, is as simple and effective as any effort of DAVID COX. In the *Hampstead Heath* we have another view which is more broken up. STANNARD'S *Coast Scene* at first appears to be a work by WILLIAM COLLINS. TURNER'S *Mortlake* shows the river as it appears looking eastward. The landscape is flat on both sides of the Thames and there are few trees, yet the place is attractive. TURNER accepted the facts and expressed the character of the scene; the river, sky and the riverside terrace are so treated that the picture is one of his most interesting landscapes. The ships in the *Helvoetsluys* might be cited as evidence that TURNER, although Professor of Perspective in the Academy, was occasionally indifferent to the rules of the science. The *Conway Castle*, by DAVID COX, is hung too near CONSTABLE'S river scene, for it now appears to be over thinly painted.

In the second gallery the Dutchmen are supreme, for the few Flemings appear as satellites. There are over fifty paintings. Every visitor should see *The Painter Dressed as a Soldier*, by REMBRANDT, in which he is seen in his youthful days wearing a steel gorget, a jewelled turban and a gold chain; his portrait of a *Gentleman with a Hawk*, another young man and handsomer than usual; his portrait of *Nicholas Berghem* and his reverential Scripture piece, *The Salutation*. Also LELY'S *William III.*; TENIERS'S *Château*, in which the painter appears as a grand seigneur, apparently to his own amusement; VAN SOMERS'S *Henry, Third Earl of Southampton*, the English MÆCENAS; and the slight but vigorous *Man and Woman with a Parrot*, by JORDAENS. An eyesore in the room is RUBENS'S sprawling *Ixion and Juno*, which was not worthy of admission.

The large gallery has about forty paintings in it, and if the enjoyment of visitors is worth considering, that number is quite ample. GAINSBOROUGH'S *Cottage Door* comes first. The engravings have made it familiar. Unluckily it has become so dark, in a few years it will be as colourless as any copy on wood or copper. GAINSBOROUGH could not emancipate himself from a belief in the necessity of a blasted tree in the foreground, but when we find he had the hardihood to introduce them in St. James's Park, they are almost excusable near the country cottage. LAWRENCE'S *Countess of Jersey* is almost ridiculous, for she appears like an ancient dancing-girl in a country theatre. Pictures of the kind are useful as a warning to portraitists and those who commission them. The portraits by ZOFFANY which appeared of late in the Winter exhibitions, prove that fame does not always come to the deserving. His *Interior of the Florence Gallery* is an example of self-sacrifice. When it appeared in 1780, it was described as "a room in the Gallery of Florence called the Tribune, in which the principal part is calculated to show the different styles of the several masters." If ZOFFANY restricted himself to a view of the Tribune, his picture would not have found a purchaser. It was necessary to introduce figures of a great many connoisseurs, who appear as if they obtained temporary possession of the place, and were able to have additional works brought into it for their delectation. ZOFFANY must have known that he could not do justice to the subject and to himself. With walls painted in vermilion, all other colours became subdued. He submitted to the inevitable, but he would not make the masterpieces of painting and sculpture appear as of less importance than the fine gentlemen. Every picture and every statue is represented with the care of a miniature-painter. The picture, if considered as a sort of conversation piece, is not effective, for the living figures appear of little account beside the works of painters and sculptors. On that account it should be prized, and ZOFFANY deserves to be remembered, for few have been the portraitists who would have shown equal courage. A comparison between REYNOLDS'S *Frances and Henry Greville as Hebe and Cupid* and his *Ugolino* suggests his weakness when dealing with imaginative subjects. The latter is deservedly skied. His *Mrs. Crewe as St. Geneviève* is as innocent of hagiology as the *Mrs. Greville* is of mythology. The fair politician is dressed in white and looks very handsome, but she is a silly shepherdess and her sheep are worthy of her. GAINSBOROUGH'S scene with the *Duke*

and Duchess of Cumberland and Lady Elizabeth Luttrell is becoming cracked, but it still gives pleasure. It would be difficult to say whether the painter was more successful in depicting the beauty of the ladies or the exaltation of the prince who is favoured by such companions. ZOFFANY'S *Life School in the Royal Academy*, 1772, reveals the main object sought in founding the Academy. It was to be a Society for the benefit of a few artists, and which by means of royal patronage was to surpass all other painters' clubs of that time. The absence of students from the picture was no oversight, for teaching was of minor importance. We learn also from the scene that in the life school the Academicians preferred to talk about the points of the model, and hence we can understand why life studies of that time are rare and why such odd figures appear in the paintings. WILLIAM HUNTER, the surgeon, alone appears to take genuine interest in the model.

The two portraits of the boy *Don Balthazar Carlos* and the portrait of *Don Gaspar de Guzman*, the statesman, are as characteristic of VELASQUEZ as any which remain in Britain. The *Virgin and Child*, if not by RAPHAEL is an excellent imitation of his manner, and it is in a remarkable state of preservation. The figure of *St. Gregory*, by VERONESE, is interesting, for the "richly embroidered cope" mentioned in the catalogue seems to be either stencilled or copied from some sort of needlework which had that character. There is a noble portrait of *Ariosto*, by TITIAN, but it ought to have been described as a replica of one in Venice, which according to WAAGEN does not represent the poet—and THORÉ agrees with him. MURILLO'S *Immaculate Conception* corresponds in the colour of the blue and white drapery with the costly work in the Louvre which SOULT carried off from Spain, but the expression of the countenance is quieter and more human. *Time Clipping the Wings of Love*, by VANDYKE, is one of the few allegorical pictures that are always likely to remain attractive. The indifferent business-like expression of the old operator is finely contrasted with the helplessness and terror of the child, and both figures are splendid in line. There is a curious landscape by GIORGIONE, an *Adoration of the Shepherds* by TINTORETTO that is vigorous in light and shade, besides a *Salvator Mundi* and a very large and very dark landscape, *Jupiter and Antiope*, by TITIAN.

If the figure of the man in JORDAENS'S portrait group could be cut out it would make an excellent picture, but the stout lady, who is the companion, could not be made attractive by any painter. The *Holy Family*, by RUBENS, may be described as a portrait group of Madame RUBENS, her boys and a nurse. The picture was evidently a labour of love, and it is not often one of the artist's works is so warm in colour without any garishness. TURNER'S *Snow Storm in Val d'Aoste* has suffered during fifty years, but it is still a most impressive rendering of a scene that portends ruin. Members of the CREWE family are the subjects of four paintings by REYNOLDS on the same wall, but the most interesting are Master JOHN posing as HENRY VIII., and Miss FRANCES as a little woman in a black coat with calash drawn over her head. It is evident that the painter must have enjoyed their assumption of characters equally with the children. LAWRENCE'S *Master Lambton* ought to be placed beside them, in order to suggest the later artist's inferiority and his inability to suggest that a subject was supposed to be seated outside a studio. REYNOLDS'S *Lady Delmé and Children* is superb. GAINSBOROUGH'S *Ladies Walking in the Mall, St. James's Park*, is a charming scene, but the few gentlemen are evidently superfluous, and are only introduced for the sake of the contrast supplied by their scarlet coats. TURNER'S *Bonneville* is last in order. It is nobly composed in large masses, to which Mont Blanc serves as climax.

The fourth room contains examples of primitive art, with some others that in style and principle differ from them, such as the elaborated portrait of PAOLO PARUTA, the historian, by TINTORETTO. Our readers will probably prefer the grand pictures by PANNINI and CANALETTO. The former lived until 1764. He was enthusiastic about ancient Rome, but as faithful copying of ruins was not considered art, and was paid for at a low price, he made pictures by grouping the remains. In those days English gentlemen who visited Rome were able to take more pleasure in ancient architecture than was possible at a later

time, for they had not been taught that Gothic buildings were alone worthy of the attention of a Christian. PANNINI, therefore, found purchasers among them, and many a *Ruined Building and Scene in Rome*, which appears without a name in auction-rooms and dealers' shops, came from his hand. Their downfall in the market, we suppose, is one of the victories of modern ecclesiasticism over paganism. In the exhibition there are two of PANNINI'S *Roman Ruins*, in which we see triumphal arches, temples, fountains, and other survivals of antiquity brought together. They are in ruins, but they are at least free from the sordid surroundings of Rome in the eighteenth century. PANNINI'S figures are well adapted to their use. In one we see a sort of CORINNE, who, we suppose, is bewailing the fall of Rome. Another architectural painting is CANALETTO'S *The Capitol at Rome*. In it we see an opposite sort of treatment. The artist believed that architecture was interesting in itself and did not stand in need of any fallacious interest. He represented the Capitol as he saw it, standing upright with every line perfectly true, and he did not consider it was his duty to make of it an object for pity. Rome had ruins enough for sentimental people. CANALETTO spared no pains in making it plain that the masonry was not decayed, but was still beautiful, and his columns, pilasters, and other details have a sharpness that is without parallel in painting. Mr. RUSKIN was supposed to have given the *coup de grâce* to the artist's reputation; but as long as a painting like the *Capitol* exists and remains inimitable, CANALETTO is not likely to be forgotten.

THE END OF THE RENAISSANCE.*

IT is as difficult to draw a line between parts of a continuous period as to give a distinguishing name to the parts. We are glad to find M. MÜNTZ avoiding the use of the term "Decadence" to designate the time treated by him in the third volume of his "History of the Renaissance in Italy." It does not seem to be an apt term when we know the character of the artists to whom it would be applicable. MICHEL ANGELO, TITIAN, PAUL VERONESE, TINTORETTO, GIORGIONE, LUINI, ANDREA DEL SARTO, CORREGGIO, SAN SOVINO, SAN GALLO, SAN MICHELE, PALLADIO can only be considered as representatives of a decadent age when the subject is considered from some very exalted point of view that is beyond the reach of ordinary men. It is better and safer to imagine that the period in question, which included a large portion of the sixteenth century, was the end of the uprising which is known as the Renaissance. The initial force was not so much weakened as diverted or changed into an agency of another kind, for in the latter days of the sixteenth century works were produced which, if seen in the golden age of the Renaissance, would have excited wonder.

We are not paradoxical when we say that the weakness of what is so often called the Decadence was an excess of power. The knowledge acquired in the earlier and the matured periods was diffused in a way that was mysterious. Every advance that was gained in art in Florence, Rome or Milan inspired artists in the humblest villages. There were no newspapers in circulation, but itinerant artists and monks were an efficient substitute for them. At all times during the Renaissance movement men were versatile, but in the third period they exhibited that quality to an extraordinary extent. It seems, for example, almost incredible that the terrible manner of MICHEL ANGELO could co-exist with the tact that was required to erect and fit up a quiet library for scholars, like the Laurentian Library in Florence. It has been subjected to hypercriticism, and it presents defects. But what is to our mind remarkable is that the creator of mighty contours was able to project himself, as it were, into another being, and become as persistent in the employment of planes and straight lines as he was before and afterwards with curves. An elephant on a tight rope could not be a more amazing exhibition of power.

MICHEL ANGELO'S own peculiarities of style became familiar wherever pictures or statues were produced in Italy. The case of ANTONIO ALLEGRI is an example. All

* *Histoire de l'Art pendant la Renaissance*. Par Eugène Müntz, Membre de l'Institut, Conservateur des Collections de l'Ecole Nationale des Beaux-Arts. III. Italie: La Fin de la Renaissance. Paris: Hachette et Cie.

the training he is known to have received was in his native village of Correggio. But his paintings prove that he was as well acquainted with the methods of foreshortening as if he had served as a substitute for MICHEL ANGELO. Some of DA VINCI'S mannerisms were no less familiar to him. Critics also perceive the influence of MANTEGNA in his works. In those days painting might be compared to conjuring, and every departure from a precedent was a trick which all artists were eager to learn. It was not a subject for speculation and discussion, but a craft, and every craftsman endeavoured to possess as many of the secrets or dodges as he could hear about. Style was a practical affair to them, and a man was not supposed to be competent until he could compel his hand to work in the manner of several artists. It is now difficult to distinguish GIULIO ROMANO'S share in the Vatican pictures from RAPHAEL'S. The assistant was so like the master, a tradition arose that GIULIO was at first the teacher of his chief:—

Thus Old Romano bow'd to Raphael's fame,
And scholar to the youth he taught became.

Yet when GIULIO was compelled to accept service at Mantua he appeared to be the legitimate successor of MANTEGNA. He not only could produce figures that might serve for a continuation of the *Triumph of Caesar* if one were necessary, but he was competent "on horror's head horrors to accumulate," and to represent dragons tearing each other in the slime or demigods ruthlessly struggling on land or among the waves. Put GIULIO ROMANO in any other city where a style had obtained ascendancy and he would be no less competent to make it his own. The adaptability of the artists was so easy, it has led to the greatest confusion, and in consequence the authorship of works in public galleries is continually varied. The late Signor MORELLI gained a reputation by his demonstration of the instability of the methods of connoisseurship in determining the authorship of pictures, and he has had many followers. In the period of which M. MÜNTZ treats, imitation throughout Italy appeared so easy it is a wonder we are enabled to have guarantees for the genuineness of so many pictures, and that the distinct styles of painting are so numerous.

An inapplicable and unjust term can do grievous harm, and there is no doubt the third phase of the Renaissance, because it was assumed to be decadent, has been under a cloud. On that account the third volume of the great work by M. MÜNTZ will probably be considered by many readers as more interesting than its predecessors. The author is exhaustive and impartial, and accordingly he renders full justice to the work of the sixteenth century. Now, most writers who treat of the Renaissance unite in devoting greater attention to the middle period, and their illustrations rarely comprise examples of the earlier or succeeding periods. The majority of the five hundred illustrations furnished by M. MÜNTZ therefore relate to works which are ignored, and on that account they will have the attraction of novelty for many readers. The student will find the advantage of not only possessing an unparalleled number of reproductions of the most suggestive examples in all departments of art, but he is also enabled to realise the mysterious variations which took place in what was the most remarkable of all the ages of development.

There are more things in heaven and earth than are comprised in any system of philosophy, and although much concerning the Renaissance is outside the scope of investigation, it is well to discover whatever research will furnish. M. MÜNTZ therefore begins by the consideration of the forces which were at work among the Italians in the latter days of the Renaissance. He treats of the influence, among others, of patriotism, government, religion, manners, morals, emotions, tradition, antiquity, realism, theories of aesthetics, &c. In his second book he discusses the state of patronage in various parts of Italy. M. MÜNTZ then applies his conclusions to the various departments of art. To architecture the third book is devoted; sculpture, painting, engraving and decorative arts, such as medals, goldsmith's work, furniture, miniatures, mosaics, glass-painting, pottery, textiles and book-binding are also explored. As an animating power which inspired them all, directly or indirectly, we have MICHEL ANGELO, whose name appears with an iteration that is a testimony to his relation with the Renaissance.

(To be continued.)

THE BRITISH ACADEMY OF ARTS IN ROME.

IN a letter to the *Times* Mr. Poynter, R.A., writes:—May I be allowed briefly to call attention through your columns to the British Academy of Arts in Rome? This institution, founded in 1823, in which many artists now well established in public estimation have in past times studied, has of late years, from various causes, retired into a modest obscurity—"in short," as Mr. Micawber might say, it has been shut. This complete abnegation of the principle that an academy to be of any use must be open for study arose chiefly from the fact that it was situated in inconvenient premises in one of the most crowded and noisiest thoroughfares in Rome, and with nothing to indicate its situation, its existence even being unknown to visitors to Rome.

This drawback has been recently removed by the transfer of the institution to convenient and well-lighted rooms forming part of a small colony of studios in the Via Margutta, a quiet street behind the Via Babuino, and in the artists' quarter.

The first rule of the Academy provides that "every British artist, on his arrival in Rome, shall be admitted gratuitously to study in the Academy on application to the Secretary."

For this purpose it is open for two hours every evening, during the winter months, for study from the living model, which is provided at the cost of the Academy, the only limitation being that there shall be not less than three students attending the class.

The Academy also contains an excellent collection of casts from the antique, which is open for study in the daytime; and there is also a good library containing many valuable works on art and general literature, from which, under certain conditions, members and students are allowed to borrow books.

By a new regulation ladies will be admitted as students and various other modifications of the rules suggested in a report recently drawn up by Colonel Slade, at the request of Sir Clare Ford, our ambassador at Rome, have been adopted, which, it is hoped, will put the Academy on a better footing and render it more useful to British artists visiting or residing in Rome.

Recently affairs have worked in a vicious circle. Under altered circumstances, and from the fact of the Academy's existence having almost dropped out of knowledge, applications for admission have declined to the vanishing point; and the discouragement arising from this cause, combined with the rule that the class is not to be opened unless there are three students to work from the model, has favoured inaction and led to the closing of the institution.

The class, established in its new premises, is now regularly open and attended by six students, and this number will doubtless be increased as the advantages offered by the Academy come to be more widely known. Things are changed, no doubt, from the days when it was thought a necessary part of an artist's education to go to Rome; but, in spite of changes of fashion and of other changes more lamentable, Rome still remains the capital and centre of art in its highest expression, and no one who would sound the heights and depths to which the noblest in art has attained can afford to ignore the lessons to be learnt there. There may still be young artists willing and able to make use of its glorious opportunities. They may find it advantageous to supplement their studies in museums and palaces by making use of the Academy life-class, and thus not altogether dropping their practical work.

Further information may be obtained from the secretary, Mr. Alex. Coleman, 53B Via Margutta, Rome.

MONASTIC LANDS AT BRADFORD.

AT the Bradford Free Library on the 13th inst., Mr. T. T. Empsall, president of the Bradford Historical and Antiquarian Society, read before the members of the Society a paper which he had prepared in continuation of one read some time since upon "Monastic Lands in the Neighbourhood of Bradford." In the course of his paper the President said that nearly the whole of the district on the south and west of the town, and to a considerable distance beyond, was formerly in the possession of monastic houses. Indeed, it might be said that for many miles in the directions named it would have been difficult to find any extensive area over which they had not more or less control. Even on the north and eastern sides, if the possessions of Esholt Priory were included, there was a wide belt of land belonging almost without a break to the monasteries. And taking the entire county into the survey, the fact became increasingly apparent to the searcher that the new field of antiquarian labour which the investigation of monastic property offered was much wider than had hitherto been suspected. The searcher found also more fully the consequences of that momentous event, the Reformation, in its agrarian aspect, and was enabled to appreciate the results of the fact that almost in a day a very large proportion of the entire county came into an unsympathetic market, to drift into

the hands of a horde of speculators, or to increase the rent-roll of unscrupulous favourites. But its entire absorption was the work of years—by gifts, sales, barter, or exchange, all the phases of which could only be ascertained through the medium of a huge labyrinth of records. But, in brief, it might be observed that the magnitude of the wealth acquired by the State at the dissolution of the monasteries was simply prodigious. Proceeding to deal with the Knights Templars, Mr. Empsall stated that in 1557 Queen Mary re-established that militant Church, and endowed it with some hundreds of small properties, among which were nearly all that formerly belonged to the late Order within the manor of Batley. Among the items in the list of her endowments of the Order were Crossley Hall, Lees Hall, Thornhill, the manor of Cottingley and Cottingley Hall, and properties at Baildon, Bingley, Hipperholme, and Halifax. Mr. Empsall then proceeded to deal with the Leaventhorpe estate, giving several incidents of its history, from the twelfth century, when it came into the possession of the Priory of Nostell, downwards. In connection with the fate of this property after the dissolution, Mr. Empsall observed that there was much jerrymandering practised with regard to the disposal of monastic land everywhere. In many cases the fact that lands had belonged to the monasteries was concealed by the tenants, and it was often only by accident that the connection was disclosed. It was doubtful, indeed, if the friars themselves were fully aware of the vast extent of many of their possessions till long after the monasteries fell into the hands of the State. He was pretty certain that such was the case with respect to Byland, Jervaulx and Sawley, all of which had considerable interests in the district. One, and perhaps the principal, cause of this was that many of their endowments at their origin were extensive areas, only partially cultivated, and so very imperfectly described and entered upon the registers of the monastery. A number of properties in the Bradford district were referred to, and the estate of the Priory of Esholt was dealt with in some detail. At the conclusion of the paper a vote of thanks was accorded to the President.

THE ROMAN VILLA AT DARENTH.

IT is now found by explorations that at Darenth, although the plan of the structure does not greatly differ from that of other Roman villas in Britain, yet some of the details of construction are of an unusual character, and illustrate in a perfect manner the eminently practical way in which the Roman builder adapted himself to his surroundings. Where stone was abundant it was used, if it served the purpose best, even for roof tiles; if stone was not to be had near at hand the pottery tile was made to take its place. In Kent chalk and clay are the most common materials, and both are made to lend themselves to the needs of the Roman architect. The chalk has been in one case roughly hewn into blocks and laid in courses to form the supports of a hypocaust. The flints from the chalk are slightly squared, embedded in mortar, and, alternating with courses of tile, form a solid wall of much the same character as is found in the neighbouring church, built at a much later time, in all probability from the material of this very villa. The various methods adopted for supporting the floors beneath which the heated air was to circulate are well shown in the several rooms. In one the pilæ are formed of flat tiles laid one upon another to the required height; in another a square pottery tube of the proper length is set on end and filled with flints and earth to increase its stability; in a third the heat is conveyed across the room by means of channels lined and covered in with tiles; while in yet another the supports of the floor (they cannot be called pilæ) are, as before stated, formed of low walls of chalk blocks. A good number of additional chambers, some of them very puzzling, have been laid bare during the past fortnight. At the west side of the villa—that next the river—a congeries of small rooms was found, some of them barely 6 feet in length, but all well finished on the walls, and the floor also, with tesserae and fine stucco. This group of rooms seems to have been served by a conduit from or to the living rooms, and it seems possible that the whole arrangement may indicate some kind of manufacture—for instance, tanning or dyeing. A careful survey of the different levels of the inlets and outlets may, however, solve the problem.

The villa as a whole seems best to compare with that discovered about ten years ago on the property of the late Mr. Dent, of Sudeley Castle, in Spoonley Wood, near Winchcombe, though this latter is scarcely so large. Both are built within a stone's throw of a clear running stream, and the two are very similar in general plan and arrangement. It is but rarely, however, that so complete and interesting an example of a Roman building is found within easy reach of London, and it is not surprising to find that, in spite of the bad weather of the past ten days, a considerable number of people, both from the neighbourhood and from London, have paid a visit to the villa.

LANCASHIRE AND CHESHIRE ANTIQUARIAN SOCIETY.

AT the meeting of this Society, Mr. J. Holme Nicholson, one of the vice-presidents of the Society, presiding, Mr. William Harrison read a paper on "The ancient Fords, Bridges and Ferries of Lancashire." He pointed out that in early times the provision and maintenance of bridges was one of the most important social duties. In times of war fords, and in later times bridges, played a very important part, and the possession of fords and bridges had been the key to the defence of many a city and province, for "if they once may win the bridge, what hope to save the town?" Mr. Harrison, following the course of some of the principal rivers of Lancashire, described the bridges, fords and ferries by which at various times they were crossed, and conveyed to the meeting a large amount of information upon this very interesting department of historical research.

TESSERÆ.

The Destruction of the Colosseum.

FOUR HUNDRED years after the time of Bede the Colosseum was a fortress in the hands of one of the noble families who fought for the domination of Rome. In this it shared the fate of all the larger buildings yet remaining from the antique time. Barons, with names like Frangipani, Orsini, Colonna, and so forth, strove for dismantled Rome like vultures for a corpse. In the Colosseum the Frangipanian birds of prey had their lurking-place. All around them was a desert. Robert Guiscard's Saracens had, at the appeal of Pope Gregory VII., stormed Rome and ravaged it with lance, the edge of the sword and fire. Then were the Aventine and the quarters between the Lateran and Esquiline seen to form one immense pyre. The walls of the Colosseum had withstood even the flames. But there came a power that they were powerless to defy—the power that had given them existence—the hand of man. Three hundred years again, and the Colosseum had become a stone quarry. Now Rome again began to be adorned with splendid palaces, for which the old amphitheatre must give a great part of the building material. The fortress-like Palazzo di Venezia that lies at the opening of the Corso, the mighty Cancelleria, Bramante's stately work, and the noble Palazzo Farnese, adorned with Michel Angelo's renowned frieze, descend both in the body and the spirit from the Colosseum, for not only the latter's blocks of travertine but even something of its Roman style did they appropriate to themselves.

Antiquity of Lewes.

The etymology of the word *Lewes* has given rise to considerable discussion, which has not thrown any great light on the subject: the Celtic, Saxon and French languages have been ransacked for a probable etymon. The hypothesis which derives it from *Hlewe*, a hill, and *Ys*, or *Ese*, water, though one of the most feasible, is liable to a great objection, since the latter expression is Celtic, while the former is Saxon; and we can hardly suppose the ancient inhabitants of the district to have given the town half a name, and to have left it to persons speaking another language, and after a lapse of some half-dozen of centuries, to complete it. There can be no doubt that both the initial and the final syllables, mean whatever they may, are derived from one language, and that that language is the Celtic seems exceedingly probable. *Lough*, in the Irish tongue, is a lake, or, more properly, any expanse of water. Now the Irish is well known to be a branch of the Celtic, the aboriginal language of Britain. *Is*, *Ese*, *Ose* or *Ouse* is another Celtic word meaning water, and is, in its latter orthography, the name of the river upon which Lewes stands. But the stranger will naturally inquire, "Where is the lough or lake in question?" and it will be necessary to inform him that until within a few centuries the level of the Ouse, both above and below the town, was a great estuary, varying in width from a quarter of a mile to upwards of a mile, and making islands of two or three elevated spots springing from its bed. It is worthy of remark that only half a century ago the pronunciation of Lewes by the rustic inhabitants of the neighbouring weald was uniformly *Lough-es*. That the district was colonised by the primeval (Celtic) inhabitants of our island is plain from the occurrence of British words as names of several localities in the immediate neighbourhood, such as Glynde, Caburn, &c., as well as from the British remains which have been discovered on the adjacent downs. There are likewise indubitable proofs that the spot was well known to the Romans; numerous relics of those conquerors, such as pottery, fibulae, rings, &c., have been exhumed in the vicinity, and many Roman coins from Tiberius to Magnentius have been found in and near the town. According to Stukeley, the great Roman road, called Ermin Street, began near Newhaven, at the mouth of the Ouse, and passed Lewes on its way to

London; and there are several traces of Roman encampments on the downs, and even, according to Mr. Elliot, within the town itself. Mr. Horsfield contends that Lewes was the Roman station *Mutuantonis*; but his arguments, though ingeniously applied, fail undoubtedly to prove the fact. That Lewes was a place of considerable importance under the Saxon rule is certain, although we find little recorded of it previously to the time of Athelstan, who granted it the privilege of two mints, while Hastings and Chichester (the only other towns in Sussex so favoured) had but one each. Hence it would appear that, so early as the tenth century, Lewes was, as it is still regarded, the county town. At a considerably earlier date the adjacent vill of South Malling had been chosen by Ceadwalla, king of the West Saxons, as the site of a collegiate church, which was annexed to the see of Canterbury. In after times that see possessed a tract of land extending from Lewes into Kent, a distance of twenty-two miles; and it is curious that a line of parishes lying in that direction is still ecclesiastically subject to the archbishop, under the denomination of peculiars.

Foreign Glass-blowers in England.

The Phœnician processes of glass-making were supposed to have been learnt by the Crusaders, and transferred to Venice in the thirteenth century, where they were long held secret, and formed a lucrative commercial monopoly. The making of plate-glass by blowing was carried on to a great extent at the village of Murano, near Venice, and Europe was long supplied from this quarter with the finest and largest mirrors. In 1575 a privilege was granted under the great seal to James Verselyn, a Venetian, for making Venice glasses, and a glass-house established at Greenwich is said to have soon blown some finer metal than that obtained from Murano. We are indebted, however, to the French for the art of casting large plates of glass, which was introduced in 1688 by Abraham Thevenart; and the French refugees improved many branches of the manufacture, especially the crystal branch, and for a great part of the eighteenth century large quantities of glass bottles were exported to Holland. It appears that in 1589 there were fourteen glass-houses in England, and a great quantity of wood was used in the manufacture; there was, therefore, a petition in that year of George Longe for a patent for making glass, urging as an inducement that he would only have two glass-houses in England, and the rest in Ireland, whereby the English woods would be preserved and the Irish superfluous woods used. (Lansd. MSS. vol. lix. 72.) About 1580 a grant was made (or prepared) for Sir Jerome Bowes to erect furnaces and make drinking-glasses and other glasses like to those made at Murano, "to be sold wholesale or retail, as good, cheap, or cheaper than those brought from Murano, and yet as good in value;" and Sir Jerome was to provide all noblemen of the realm with sufficient store of drinking-glasses, well-fashioned, to be made in Murano or Venice, at reasonable prices, as theretofore sold for. This grant was not to commence until the expiration of a grant for twenty-one years to James Verselyn, dated December 15, 17th Elizabeth, and might be revoked in case of future amity with Venice. (Lansd. MSS. vol. lxvii.) About 1670 a number of artists, the principal of whom was Rosetti, came from Venice, and were patronised by the eccentric Duke of Buckingham; and a manufactory was established at Vauxhall, and was carried on with great success in the firm of Dawson, Bowles & Co., excelling the Venetians and every other nation in blown plate-glass for looking-glasses and coach windows.

Experiments in Acoustics.

It is a fact well established by observation, that when two bodies are in perfect unison, and separated from each other by a space filled with air, the vibrations of the one will be transmitted to the other. From this consideration it is probable that very nearly the same effect ought to be produced in transmitting immediately the vibration of a tuning-fork to a reflecting body, as to duration and intensity, as in the case of transmission through air. This conclusion is strengthened by floating a flat piece of wood in a vessel of water standing upon a sounding-board; placing a tuning-fork on this, the vibrations will be transmitted to the board through the water, and sounds will be produced of the same character as those emitted when the tuning-fork is placed directly on the board. The fork was next placed upon a large thin pine board—the top of a table. A loud sound, in this case, was produced, which continued less than 10 seconds. The whole table, as a system, was thrown into motion, and the sound produced was as loud on the under side as on the upper side. Had the tuning-fork been placed upon a partition of this material, a loud sound would have been heard in the adjoining room; this was proved by sounding the tuning-fork against a door leading into a closed closet. The sound within was apparently as loud as that without. The rapid decay of sound in this case was produced by the great amount of motive power of the fork being communicated to a large mass of wood. The increased sound was due to the increased surface. In other words, the shortness of duration

was compensated for by the greater intensity of effect produced. The tuning-fork was next placed upon a circular slab of marble, about 3 feet in diameter and $\frac{3}{4}$ inch thick; the sound emitted was feeble, and the undulations continued 115 seconds, as deduced from the mean of six experiments. A cylindrical piece of indiarubber about $1\frac{1}{4}$ inch diameter was placed in a tubulated bottle with two openings, one near the bottom and the other at the top; a stuffing-box was attached to the upper, through which a metallic stem, with a circular foot to press upon the indiarubber, was made to pass, air-tight. The lower tubular was closed with a cork, in a perforation of which a fine glass tube was cemented; a small quantity of red ink was placed in the hole to serve as an index. The whole arrangement thus formed a kind of thermometer which would indicate a certain amount of change of temperature in the enclosed air. On the top of the stem the tuning-fork was screwed, and consequently its vibrations were transmitted to the rubber within the bottles. The glass was surrounded with several coatings of flannel to prevent the influence of the external temperature. The tuning-fork was then sounded and the vibrations were kept up for some time. No reliable indications of an increase of temperature were observed. It is evident that an object like indiarubber actually destroys a portion of the sound, and hence in cases in which entire non-conduction is required, this substance can probably be employed with perfect success. The tuning-fork was next pressed upon a solid brick wall; the duration of the vibration, from a number of trials, was eighty-eight seconds. Against a wall of lath and plaster the sound was louder and continued only eighteen seconds. From these experiments we may infer that if a room were lined with a wainscot of thin boards, and a space left between the wall and the wood, the loudness of the echo of a single noise would be increased, while the duration of the echo would be diminished. If, however, the thin board were glued or cemented in solid connection with the wall, or embedded in the mortar, then the effect would be a feeble echo, and a long-continued resonance similar to that from the slab of marble. This was proved by first determining the length of continuance of the vibrations of a tuning-fork on a thin board, which was afterwards cemented to a flat piece of marble.

Romanesque Plans.

In the great majority of buildings—perhaps in all cases where Pagan architecture was employed—the plan is found to be exactly that of the ancient basilica or hall of justice; that is, a parallelogram or nearly a double square, with the semicircular or octagonal recess at one end, usually called the apsis—in the court-house, the judge's seat; but in the church, the sacred place where the altar was placed, and round which sat the bishops and presbyters. In some examples the atrium adjoining was retained, as at San Clemente near Rome and San Ambrogio at Milan; and which, in appearance at all events, would appear to bear some analogy to the more modern cloisters. In some of the later edifices we observe the transeptal arms broken out, as in a Gothic cathedral; but by far the most usual is the simple Latin plan—though we do see some examples of the Greek cross; but these must in all cases be put down as the work of Greek architects, for the Latin architects never altered the more ancient form to which they were accustomed. This simple plan so much preferred by the early Christian church may be traced through the Romanesque to the Gothic, and there can be no doubt it was the excellent basis which lies at the root of all the variations which that style engrafted upon it. This form of plan was used by the early Christians, doubtless because in many cases they found it ready presented before them in the already existing basilicas, which they easily converted into churches; and secondly, because its simplicity was admirably adapted to their wants—the central nave and two side aisles, the northern assigned to the women, the southern to the men; the centre occupied by the choir and sub-deacons, then by the neophytes and candidates for baptism; and lastly, near the door, by the penitents. This simple plan was extended and added to subsequently, though always preserved as the main principle of arrangement, particularly in the neighbourhood of Rome; and the alterations such as the addition of transepts, &c., are much the most usual in Lombardy. The single apsis was never forgotten, but others were added at the end of the aisles, then to the transepts; and as the fashion of building chapels to tutelary saints became more in vogue, they were even broken out laterally. In all the earlier instances the floor was level, except only two or three steps to the apsis, where the high altar was situated; but as the prejudice against burial within the consecrated walls died away and as the Church began to build for itself, we find the introduction of a new feature in the plan and which is treated with the utmost importance—the crypt, which in these edifices appears not as a place of sepulture, but as a sort of lower church, complete with its altars and shrines; supposed by some to have been erected in imitation of the catacombs—those early places of meeting in which the early Christians were wont to hide themselves and to carry on their

simple but sincere worship. Whether this be a mere fanciful supposition or not, what we know is that they were prepared for the reception of the bodies of confessors and martyrs; and as such were treated with as much care and attention as the rest of the church—not sunk into the earth, but often nearly on a level with the floor of the nave, and with a number of steps ascending to the choir above (which had then been removed from its first position in the nave), just as we see it at Canterbury. It is thus at San Miniato at Florence and at San Flaviano near Montefiascone, where there is a complete lower as well as upper church; at San Francesco at Assisi where the saint was entombed, at San Zenone at Verona and many other places. This custom of building crypts and subterranean chapels was continued in the architecture of our own country until the last half of the eleventh century, but probably not much later.

Changes of Style.

There are certain periods in the history of the world, or of individual nations, when some great public event, some discovery, or some cause which deeply affects the public mind, produces a corresponding change in art also. Such for instance, in civilised Europe, was the change produced by the discovery of printing, and the dissemination by its means of the writings and thoughts of the ancients. These led to the study and contemplation of those fragments of antique art which had survived the injuries of time and barbarism, and through their study to reconstitute beauty as the prevailing principle of art, to the subversion of the religious sentiment which had, for many ages, been its leading and all-pervading idea. Again, when from political changes art became gradually estranged from its Italian cradle to be fostered by the growing power of the French kings, and when the victories of the Fourteenth Louis had gained him the title of the Great Monarch, art also was led captive in his triumph. No longer satisfied with beauty, she decked herself to please him in "barbaric pomp and gold;" splendour and display became her ruling principle, and the style called after his name was formed. As we approach still nearer our own era other changes, not so marked, but equally characteristic, might be noticed as influencing art through changes in the outer and surrounding world. All these changes are clearly discernible to us who look back upon them; we can even trace them to apparent causes; but rising gradually and imperceptibly in their own age, they were then not clearly noted as points of departure, or as sufficiently influencing the prevailing taste to form a new and distinctive style.

Conventional Treatment of Natural Objects.

It must be remembered that absolute imitation, difficult in fine art, is almost impossible in many manufactures, whether by hand or by the machine, and therefore imitation can be but a question of degree. Take for instance the application of art more peculiarly to manufacture by machinery, say that of calico-printing. Here the precise imitation of natural objects is impossible since relief is unattainable, although the appearance of relief may be given by light, shade, perspective and colour. But is the mode or degree of imitation peculiar to the artist flower-painter that which is most suitable or conducive to the desired end? In the first place, the processes of production control the application of colour, which must be laid on in separate and unblended masses by means of machinery, and not by that curious and delicate instrument the human hand, while the several tints also must be applied by successive and distinct processes, so that it would seem scarcely possible that calico-printing could compete with the imitative means at the disposal of the flower-painter. Let us, however, allow that by improved mechanical and scientific aids the imitation of flowers, foliage, or other natural objects in light, shadow, growth, colour and relief could be rendered as perfect by machinery as it is by a Van Huysam or David Seghers; still the art is to be applied to a specific use and not to be examined as a picture is. The fabric on which the painting is to be impressed is partly transparent, and the forms are at once blurred and indistinct; the garment it is intended to be made into is to hang full and in folds; thus the light, shade and the very forms of the object which has been imitated are confused and hidden, and that imitation which the manufacturer has been at such pains to produce is entirely lost and destroyed. The garment moves with every motion of the wearer, and any examination of this rare art, as we are enabled to examine the painter's work, is, in the use of the material, as impossible as it is undesirable. Printing again necessitates a constant repetition of the same details; and what would be said of the painter who, instead of a rare flower or group of flowers, offered for our admiration a dozen or a hundred of the same monotonous form, the same unvaried colour, the same tedious arrangement of imitation? If the painter's imitation is sought for by the calico-printer, let at least each flower, each sprig, each group be varied and different. But no, such is not the end in view: it is not to imitate the painter, it is not to

attempt to vie with nature, that is the true aim of the calico-printer; the legitimate art to be applied to such fabrics is at once seen to be simply to decorate or enrich the surface with agreeable forms and colours, and if for this purpose we use the beautiful forms and colours of natural objects, we must use them consistently with the true use and purpose of the material and the means at our command to produce the effect sought for. As the machinery by which the art is reproduced acts by a constant repetition, a geometrical distribution of forms is more or less a necessity which cannot be overcome. As the tints must be laid on separately and successively and cannot be softened or blended, the simplest combination of tints and colour must be sought for rather than the more intricate; a circumstance also called for by the market offered for such goods. If varied hues of colour are introduced to be agreeable to the eye, colour must be distributed according to fixed laws of quantity and juxtaposition, which is scarcely attainable by that mode of imitation which is called naturalistic, but which lends itself readily to that symmetrical and regular display of the plant which is called a conventional treatment, a treatment shown to be consistent with the natural laws of the growth of plants, as it is with that simple impression which flowers in their natural state of growth make on the casual observer.

The Bernardi in Sussex.

Theodore Bernardi and his two sons, Antony and Lambert, were brought to England by Bishop Sherburne in 1519. From Dallaway's examination of the parish registers in Chichester it appears that Antony, the son, died in 1619, aged 105; he was, therefore, only five years old when his father came over to work for Sherburne, and the paintings executed at that time must be attributed to the father, Theodore Bernardi, alone. A part of his paintings in Chichester Cathedral, *quasi*-portraits of the sovereigns of England from William the Conqueror to Henry VIII., were absolutely destroyed by the fall of the spire, February 21, 1861. The rest were taken down when the ruins were cleared away, and have been preserved and refixed, though not in their former position. The two great pictures referring to the foundation of the see by St. Wilfred and Ceadwalla, the Saxon king, and the patronage of it by Henry VIII., are now at the back of the choir stalls under the great arch of the south transept. The portraits of the bishops from the foundation of the see are now in the north transept, under the great window at its north end. For the history of art these works had lost much of their interest in consequence of their treatment by Tremaine; but there is in existence a series of untouched paintings, unquestionably by the elder Bernardi. These paintings are at Amberley Castle, Sussex. This castle, in Sherburne's time, was one of the residences of the Bishops of Chichester. An upper chamber in it has still considerable remains of oak panelling, of Sherburne's time, and bearing his initials, R. S., carved as well as painted. In the panels are painted a series of female figures, the meaning of which was long a puzzle to antiquaries. The series consisted of nine portraits; of two of them now very little remains, and their remarkable coats of arms identified them as a series of "The Nine Worthy Women of the World," which painters and romancers of that period were fond of delineating, the artist or the poet being very much given to make his own choice as to the personages to be enrolled in the Worthy Nine. Amongst those depicted at Amberley we have Semiramis, Queen of Babylon; Thamaris, Queen of the Massagetæ; Queen Sinopis of "Ennay;" and Cassandra; with, probably, Minthia and Hippolita, Amazons. All of them had explanatory legends, but these were painted out, most likely, in the time of Charles II., when some additional painting was certainly done in the room, and are now only partially displayed afresh. Although the margins were thus repainted, the pictures themselves were not interfered with, and Robert Sherburne's initials, R. S., may still be seen upon some of them. These must be regarded as highly valuable specimens of Bernardi's work. His sons continued to exercise their father's profession in Chichester, and apparently in a descending scale. Lambert Bernard, son of the before-mentioned Lambert, was baptized in 1627, and is probably the same "Lam. Bernard, Pict." whose name was noticed on the cathedral weathercock when it came to the ground in 1861, with the record that he gilt it in the year 1675. To the first Bernardi, commonly believed to be Theodore, it is usual to attribute a good deal of Renaissance arabesque work which at different times has been exposed from beneath more modern coatings on the nave vaultings of Chichester Cathedral, and which is to be seen very extensively on the vaulting of the choir of the neighbouring abbey church of Boxgrove. Although the head of the Bernardi family is commonly called Theodore, it is worth notice that in Bishop Sherburne's own papers, as pointed out by the Rev. G. A. Clarkson ("Sussex Archaeological Collections," vol. xvii. pp. 211, 212), "Lambert Bernardi, the painter," is at least twice mentioned, and there is no mention of Theodore.

NOTES AND COMMENTS.

THE Lord Mayor of Liverpool appears to have been taken to task for an utterance in his speech in aid of the unemployed. He may not be exceptional in urging the claims of the necessitous, but for the sentimental folk it would seem that he put in too plain language that the vagabond unemployed spoil the opportunities of those willing to work. Too many of the unemployed, it is well known, prefer wages to labour. If work is offered to them it is refused, though they condescend to accept half-crowns if it involves no exercise of their muscular limbs. These stand in the light of those unemployed who are only too willing to give a day's work for a moderate wage when times are bad. The Lord Mayor should probably have been more sentimental. He should not perhaps have used language so blunt, though so appropriate and so understandable. His words as reported mean that one cannot help those who will not help themselves; that they must be let "go to the devil." He could have said, "If mankind cannot help them, they should apply to angels." The Lord Mayor should rather have been praised for pointing to the fact that so many refuse work and then come as paupers on the country under the specious term of "the unemployed."

THE painting of the Hammersmith Bridge was a source of amusement to all who passed while the operation lasted. It was a fascinating spectacle for the building workman. It might have been an object-lesson devised with the intention of convincing him that when the contractor was abolished and all works were controlled by a county council, then labour would become a pastime. The people of Hammersmith became anxious about their share in the experiment, but they were persuaded that the playing with colours would not be more costly to them than to remote parts of the Metropolis. The estimated cost of the work was 1,000*l.*, which was a very large sum for one bridge. Then by manœuvring 50*5*l. was voted for extra work. It was revealed on Tuesday that the expenditure was 2,186*l.* In 1888 the cost of the painting was 85*5*l. It is needless to say the bridges committee declared that no fault was attributable to anybody. But a great many experts could be produced who would maintain the contrary. Whether the men were to blame for enjoying themselves when an opportunity was given them to have a prospect of Thames scenery is an ethical question over which modern moralists will differ. It is evident, however, there must be no attempt at criticism of any extravagance over what is termed labour, for Mr. JOHN BURNS threatened to "whip the Moderate Party hand and feet if they dared to go against labour and in favour of the contractor."

RICHMOND PARK has only one suitable approach from London. But the streets of the town are not the most desirable for riding or driving. The pleasantest way is that known as Priory Lane, which leads from the main road to the park. It has the appearance of belonging to a property that is in Chancery, for it is not kept in good condition. Foreigners must be amazed when they pass along it, for in no other country is a public or royal park reached by an avenue that is so neglected. The Office of Works would desire to see Priory Lane widened and properly kept, and suggestions have been given to the London County Council on the subject. The work would cost 11,000*l.* or 12,000*l.*, which is a large sum to pay for an improvement that would be at least as beneficial for the county of Surrey as for the Metropolis. There is a third interest which is to be considered, and which is more direct—that of Wandsworth. The propositions of the District Board are to pay a sum of 5,000*l.* if the London County Council will form the approach, to acquire the necessary land and buildings, and to re-erect the fences which will have to be set back. The expenditure that way would be insignificant, for the fence is only a wooden paling, and the only building is a cottage that is as neglected as the road. As the London County Council is in a moribund condition, the improvement committee do not care to meddle with an undertaking that can only be described as having utility, and could not be readily turned to account as an advertisement. The improvement is therefore to be dropped, on

the ground that whenever the adjoining land is laid out for building the owners will have to set back their building line. So far the game has been played by the Office of Works assigning the duty to the County Council; the Council passes it on to the Wandsworth District Board; the Board returns it to the Council; and the Council is now on the look-out for the victim who will have to undertake it at his own risk.

ACCORDING to the late Professor FREEMAN, the greatest building of Aachen is a direct copy of the greatest building of Ravenna, and it is only while we keep within the shadow of his minster that we really feel we are in the city of CHARLEMAGNE. From its architectural as well as historical importance the old minster cannot be watched too carefully. We hope, therefore, it is through an excess of interest in the preservation of the minster, rather than through their militant propensities, that the civil and ecclesiastical authorities of Aix-la-Chapelle are at loggerheads over the custody of the building. The "Staatsprokurator" claims the responsibility on the ground of being president of the body that was founded in 1849 in order to raise money for the restoration of the building. He considers that from his office he has a claim on the building, in order to be sure that what remains of the subscriptions is properly expended. But the clergy can refer to ancient precedents to support their position as proprietors for the time being of the building. Moreover, it was declared by the founders of the restoration fund that the control of the clergy over the minster was not to be changed. It has yet to be discovered what action will be taken by the Archbishop of Cologne in the affair, but it would be hard to expect from him a decision in favour of the secular authority.

THE report which M. GUADET has published throws some light on the decision of the judges over the designs for the Exhibition of 1900. There was no need of voting about the designs which were awarded the highest and lowest classes of prizes. The second and third classes alone gave rise to differences of opinion. The conclusion of the judges was that the task of designing and superintending the execution of so colossal a project is beyond the power of a single architect, for what is contemplated is the creation of a novel city. The use of the competition was in obtaining a remarkable diversity of ideas which could be utilised in preparing a definite plan. Every design in which it was proposed to cover the Seine was eliminated. Some of them showed much talent in the palaces of arts or of *fêtes* which were proposed to be constructed over the river between the Champs Elysées and the Esplanade of the Invalides. Other excellent designs which contemplated the destruction of several trees were also rejected, for the judges would not tolerate the infliction of an enduring injury to Paris for a temporary necessity. The bridge which is required was approved with hesitation; and on the understanding that it would be in a position to always appear in line with the dome of the Invalides. The Palais de l'Industrie, in which the exhibitions of the Salon are held, is doomed, for its removal will enable some splendid perspectives, taking in both sides of the river, to become feasible, besides allowing of easier communication between sections of the exhibition. As regards the Eiffel Tower, the judges suggest that it will be preferable to leave the lower arches on the ground open as at present, rather than to fill them with conservatories or winter gardens. In conclusion, the judges are unanimous in testifying to the abundance of original ideas, the boldness of the conceptions and the artistic merit which the competition called forth, and which were worthy of the French school of architecture.

M. DETAILLE has been elected President of the Société des Artistes Français, an office for which he is qualified in every respect. Whether he will be able to display at the next Salon the portrait of the Prince of WALES which was commissioned by the Emperor of RUSSIA, is at present uncertain. M. BONNAT, who was M. DETAILLE's predecessor, will remain attached to the Society as honorary president. M. CHARLES GARNIER, the architect, is one of the vice-presidents.

ILLUSTRATIONS.

[THE HISTORY OF CLOVIS...NO. III.]

IN the painting which we reproduce this week, M. BLANC has represented the issue of the combat in favour of CLOVIS and the Franks. M. BLANC'S work is remarkable for his success in depicting figures in most difficult positions,

SEDILIA, ST. PAUL'S CATHEDRAL.

THE illustrations show two more of the late Mr. ANDREW HEITON'S works, and will, with the others given, suggest his versatility as an architect.

SOCIETY OF ARCHITECTS.

THE meeting of the Society took place on Tuesday, the 15th inst., Mr. Hamilton, president, in the chair. Mr. F. Aumonier read the following paper on "Wall-papers: their Manufacture and Design."

Mr. AUMONIER said the first consideration for the manufacture of a wall-paper is the choice of suitable materials: paper, colours, mica-powder, bronze, flock, size, &c. The paper is bought by the paperstainer in huge rolls or reels, each containing about eighty pieces of 12 yards each, or rather more than half a mile in one continuous length; the colours are obtained of colour-makers mostly in a pulpy state, unsized, but otherwise ready for use, in great casks, and they are mixed with one another, and with black and white, to make all tints. Their first essential to meet present public requirements is that they shall be non-arsenical in their nature, and next that they shall be reasonably fast to light, a matter to which great attention is paid, especially by the leading block-printers. Powdered mica is made from the waste pieces left from the manufacture of mica plates for covering gas jets and for other purposes, crushed into dust. Bronze powder is too well known to need description. Flock is wool cut or ground to a powder and dyed to any tint; and size is made from the skins of animals, and is a perfectly sweet and wholesome material, practically imperishable in a dry atmosphere. After the materials are provided come the manufacturing processes, the first of which is colouring the grounds. These may be dull or body grounds, satins or micas, and they may be coloured by hand or by machine. If colouring by hand is decided on, then the process is that illustrated by the two slides showing a hand-colourer and his boy at work. The man has a large round brush in either hand; with his right-hand brush he lays a broad streak of colour down the middle of the piece; he then roughly spreads it with both brushes; his boy follows him with a square brush; the man then takes a clean brush in his left hand and lightly smooths the wet surface of the colour, leaving it finished and practically free from brush marks.

If coloured by machine, the reel of paper is adjusted to the machine, the end of it is passed over a flat table covered with a revolving endless felt or indiarubber band of the full width of the piece, and in the course of its progress the surface of the paper is first covered with colour and then smoothed by contact with brushes, leaving the machine with a perfectly even coating, when it is automatically hung up to dry. When satin is required, the paper goes through one or other of these processes with a specially prepared colour, and when dry it is rubbed over with powdered talc and polished by friction. When mica is required, the wet colour is dusted over with the powdered mica, which adheres to it firmly. The choice of a design and the cutting of the blocks are the next operations. The design for an ordinary English paper should be 21 inches wide, and of a not greater length. The most careful attention must be paid in the drawing to ensure correctness of fit when repeated, both horizontally and vertically, and no pains can be too great to prevent the recurrence of bad, unintentional lines, when hung this being one of the most common and troublesome defects, even in the drawings of experienced artists. The drawing is put into the hands of the block-cutter, who makes a careful tracing of it, transfers the design to the block, and cuts away the parts not required, leaving the design in relief ready for printing. If the pattern is in one colour only, it is finished in one block, but if of many colours, a separate colour is required for each. The blocks, which are made of deal faced with pear-tree wood, have little points at the corners, by means of which an accurate fit is insured, both on the repetition of the leading block and on the

succession of other colours. Broad massive patterns are cut entirely in wood, fine ornaments and small details are put in in metal, bands of thin copper being bent or filed to the shape required and driven edgewise into the wood bit by bit until the design is completed. The printing-table is extremely simple in its arrangement, consisting of a strong frame with a hard wood or stone bed about 30 inches by 36 inches, with two levers, one near the floor and one overhead, joined by an upright bar, enabling the printer by an easy motion of his foot to give the block any amount of pressure required. These printing-tables look so very primitive that it is difficult to imagine that nothing better can be found for the purpose. Specifications of several inventions intended to replace them moulder in the dust at the Patent Office, while the old tables have outlived them all, remaining now much the same as they were a hundred years ago, and all the beautiful works shown by English makers at the great international exhibitions were printed upon them. By the side of the printing-table is another strong frame supporting a shallow case lined with lead, called a "slush box," in which is a wet pulpy mass covered with a waterproof cloth. On this the colour sieve is laid; a boy spreads the colour evenly on the sieve, the printer dips the block into it, transfers it to the paper on his table, presses it, and goes on repeating the operation until the piece is finished, when it is hung up to dry at the ordinary temperature of the atmosphere. In many-coloured papers the prints are successively laid and fitted in their places by means of the little pins at the corners, and there is practically no limit but the sordid one of cost to the number of colours that may be used.

Of late very artistic effects have frequently been produced by printing in transparent colours (specimens of which are on the walls), and there is a great field open for the further development of this process, or a combination of transparent and body colours. Some decorators have private designs in skeleton form printed for them in one colour, and produce uncommon and often pleasing effects by finishing parts of the pattern by hand-painting or stencilling. There are many subdivisions of block-printing, which it would take too long to describe in detail. One is the making of stripes, which are now much in demand. A brass box or trough, of V shape, is made; the bottom is perforated with openings of the widths of the stripes required. This is adjusted to a hand machine and filled with colour, the paper passes between the box and a drum covered with an endless felt, which is turned slowly round by one boy, while another walks backwards with the finished paper until the piece is completed. Another minor process is embossing, an operation by which a grain or figure is given to the surface of an otherwise finished paper. A device is engraved upon a metal roller, upon which rests another roller of double the circumference, made of paper put in sheets edgewise on a spindle and squeezed up very tightly by hydraulic pressure. The two rollers are together under pressure until the device engraved on the metal roller is impressed upon the other, when the paper is passed between them, and receives the impression of the engraved device, which it retains permanently. Such embossing gives shadow and some relief from the monotony of an otherwise flat surface. Flock is a beautiful material, to the working of which great attention has been paid from the time that paperstaining first became one of the industrial arts. It is not only very fine in effect from the great richness of its colour and the texture of its surface, but it is susceptible of treatment in a great variety of ways, and is very durable.

The records of the Patent Office date from before the Great Fire of London, but I believe that even earlier than that a royal charter was granted to a French refugee for the manufacture of flock papers for wall-hangings, and it is certain that very many patents have since been taken out for improvements connected with its application to wall-papers. Amongst the most important of the ways in which it is turned to decorative account are raised flocks, which are either coloured, or in the white for painting over. By far the greater part of those made at the present time are on coloured grounds, and they are hung without painting until they are soiled, when a coat of paint makes them again fresh and bright. The great picture-gallery of Buckingham Palace is hung with one of the designs shown, painted and shaded in imitation of silk, but the colour used there is a cold grey, not very pleasing as a background for pictures. Other designs were shown for dados, walls and ceilings. These papers are easy of application, very inexpensive compared with other materials producing a somewhat similar decorative effect, the back is solid, allowing no harbour for vermin, and they are free from any offensive smell. The raised designs look so sharp, and are left with such a fine even surface, that many people imagine they are in some way cut out or stamped, but such is not the case. They are printed in a very sticky oil colour, the printed paper is passed into a drum with a linen bottom (as shown on the screen), the flock dust is thrown upon it, and the drum is beaten vigorously with a cane, causing the flock dust to adhere to the oil colour and form an even coating. The

two operations of printing and flocking are repeated time after time, until the required amount of relief is attained, the sharpness of the arris and the general evenness of the surface being dependent upon the skill of the operator. Silk flock, and flock on a silk background, are the most modern and the richest outcome of one branch of the paper-stainer's art. There is an idea abroad that flock, green flock especially, is highly arsenical, but it is not founded on fact, as no arsenical preparations are used in dyeing this material. With respect to arsenic generally there is now but little apprehension as to wall-papers containing this poison. All the principal makers have abandoned the use of arsenical colours, and the danger is now rather that a wall-paper free from arsenic will be erroneously condemned as arsenical, than that an arsenical one will be passed as harmless. The action of the National Health Society in establishing a standard test for arsenic has done much good, but to use it effectually it is essential that all reagents should be most rigorously tested before they are relied upon.

With reference to machine-printing, there has been an extraordinary development within the last decade. During the earlier part of this century there was a very high protective duty on the importation of foreign paperhangings, as much as 1s. per yard super (*vide* "Cyclopædia of Useful Arts and Manufactures," p. 273), and paper-stainers, having little to fear from foreign competition, did not over-exert themselves to improve their trade. Nevertheless there were many applications lodged for letters patent in connection with the art, and not a few of them aimed at the production of what are now called "engraved" or "sanitary" papers; but the processes were crude and clumsy compared to those now used, and the patents were either not carried beyond the stage of provisional protection, or were allowed to fall into abeyance. The first great cause that gave importance to machine-printing was the invention of Gamble and Fourdrinier, the practical result of which was the manufacture of paper in continuous lengths. Prior to that pieces were made up into 12-yard rolls by sheets joined together, and the paper-stainer had to await the arrival of the exciseman before he dared to use the pieces so joined. Fourdrinier's invention was followed by one to effect the more rapid drying of machine-printed papers by a system of boxes heated by steam, and when these inventions were followed in 1861 by the total abolition of the paper duty, a fresh and vigorous impulse was given to machine-printing, improvements in which are still constantly being made.

The factory of Messrs. Allan, Cockshut & Co., of Old Ford, is equipped with every known contrivance for turning out the best machine-printing it is possible to produce, both surface-printed and engraved. The works extend over nearly three acres of ground, covered for the most part with modern fire-proof buildings filled with beautiful and ingenious machinery. For surface-printing the design is outlined with copper bands driven edgewise into a wooden cylinder, and the solid parts of the pattern are filled in with fine felt cemented to the bottom of the spaces between the copper walls. The rollers are adjusted to a powerful machine as shown by the diagram. Each colour has a roller to itself, and is provided with colour-box and endless sieve, which supply it with colour, and it rotates on its own axis round a revolving big drum. The paper is passed between the drum and the rollers, receiving the printed impression from each in turn, and leaves the machine finished. It is then automatically carried into the drying-room, which it traverses from one end to the other, turns round, still automatically, and slowly makes its way back to near its original starting-place, dry and ready to be rolled up. The animal size of the block-printer is replaced by various kinds of gums that bind the colours firmly to the paper, and which do not suffer from the great heat to which the papers are subjected in drying, which would spoil sized colours.

Engraved, or "sanitary" papers, to give them the title by which they are best known, are printed in varnish colour from designs engraved on copper cylinders, and some of them are beautiful interpretations of the original drawings, the process lending itself well to the reproduction of artistic effects.

In the first place the design is transferred to the roller by a photographic process, after which it is engraved entirely by hand. The ground of the paper and the high lights of the ornament are left clean and bright in the copper, the printing being done only from the indentations, the same as in copper-plate engraving. The machines for printing these papers are very heavy and strong, on account of the great weight of the rollers, and it is found desirable to have a separate engine for each printing-machine, in order to insure greater rigidity and a more perfect control over the rate of speed at which the machine is run. Briefly, the engraved roller revolves in a bath of coloured varnish, by which the lower part of it is entirely obscured while the upper part is kept clean and bright by a doctor, which removes all the superfluous colour, and the roller on contact with the paper prints only the colour left in the sunk parts. The doctor

is a thin plate of hard steel set dead true against the copper roller; and it speaks well for the perfect accuracy with which these machines are made that such delicate work can be done in an almost faultless manner, and at a speed which secures for the manufacturers a remunerative profit, although such papers sell even retail at very low prices.

A table was shown of samples of various tints with their relative money values, varying from 1 to 250, the object being to remove a prevalent misconception that change of colour has no appreciable effect on the cost of a wall-paper. Great stress was laid upon the importance of cleaning off all old papers before putting new ones on the wall, and specimens were shown of masses of ten or more thicknesses of paper recently stripped off the walls of good houses in the West End.

Slides were shown illustrating wall-paper and decorations by well-known artists, all block-printed and in many styles, several of which were exhibited at Chicago; and a general view of Messrs. Wm. Woollams & Co.'s stand at that exhibition was also shown.

A vote of thanks, proposed by Mr. Lovegrove, seconded by Mr. H. Goodall Quartermain, and supported by Mr. Crace, Mr. Essex, Mr. Allport, and Mr. Heaton, was passed to Mr. Aumonier for his paper.

SCOTTISH NATIONAL ARCHITECTURE.

A LECTURE in the Corporation Art Galleries, Glasgow, was delivered by Sir John Stirling Maxwell, Bart., of Pollok, on the subject of "Scottish Architecture." The lecture was one of the Corporation art series. Ex-Bailie Shearer presided, and there was a large attendance. Sir John at the outset said he would try to show them that Scottish architecture displayed an orderly development which could be easily traced and understood. The earliest buildings they had to notice were churches, although churches were much less distinctively Scottish than domestic buildings. The Norman Conquest did not extend to Scotland, but Malcolm Canmore and his successors welcomed Norman and Saxon immigrants in such numbers that this country shared all the advantages of the Conquest without any of its oppressions. This was the great church-building period all over Europe, and Scotland was not behind other countries. Nearly all the Episcopal sees and great religious houses were founded at this time. Holyrood, Melrose, Kelso, Jedburgh and many others owed their existence to the generosity of David I., and it was no wonder James I. called him "a sair sanct for the Crown." The little church at Dalmeny was as beautiful as anything of the time in France and England. After 1236 there was an architectural hiatus of a century, in which gap the church of St. Monance, in Fife, stood nearly alone. After 1424 a number of collegiate churches were built; and later on they saw the French influence in such buildings as Trinity College Church in Edinburgh—a church which had been swept away by the North British Railway Company to make room for the Waverley Station. Roslyn Chapel and St. Giles's, with its crown steeple, and one or two Gothic churches, were next alluded to, before reference was made to the domestic buildings. The earliest castles they had in Scotland were of the thirteenth century, and Bothwell Castle, Mearns Castle, Rothesay Castle, and Borthwick Castle—the latter with the most majestic fireplace in Scotland—were touched upon and their special features pointed out. Building revived in Scotland under James I., and the Reformation helped to account for the very large number of houses which were built at this time. The castles of this period afforded the commonly accepted type of Scottish architecture. Maybole was a good example of the so-called "L" plan, and Castle Fraser was an example of the "Z" plan. Fyvie was a later example of the Scottish style, and was the most imposing castle in Scotland still inhabited; but it showed signs of the invading Renaissance. When they looked at Argyll's Lodging in Stirling, built thirty years after Fyvie, the extravagant turrets and corbelling were all gone. The roof and gables had reasserted themselves. This was a beautiful type of a large town house, and was the type which held out the best future for a national architecture in Scotland, if people would only be less ambitious and condescend to look at it. It was quite suited to modern habits, and it all seemed ready and waiting for the touch that could change it into a perfect modern house. Heriot's Hospital gave them some notion of the last strange efflorescence which architecture made at the time when it fell into the stifling embrace of the Renaissance. The lecture was illustrated with a series of photographs and drawings.

The Meeting of the Liverpool Architectural Society, which was announced to be held on Monday, the 14th inst., was postponed.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

A MEETING of the Institute of Architects took place on Monday evening, when Mr. F. C. Penrose, F.R.S., president, delivered the annual address to students, his subject being entitled

Study of Buildings To-day and in the Past.

The PRESIDENT in alluding to the examinations said that care had been taken to make the examinations of the Institute, whilst being a fair test of efficiency, yet not so severe as to be an inaccessible bar to any whose talents showed real sympathy with the profession of architecture. Besides drawing and the practical studies of construction, there were some subjects which the student should recognise as not unconnected with architecture, namely, geology and archæology. Good architecture in all time had been the development of what has gone before, and unless the new was well keyed into the old there was no reasonable prospect whatever of success. Too close an adherence to the past was also to be deprecated, except in the case of those who might be engaged in the restoration of churches and other ancient buildings. In works of that nature archæological conditions should be paramount, or only controlled by the requirements of Divine service or other necessary use; but it should be historical archæology and not selective. In restorations it was scarcely possible to be too conservative. It had not infrequently happened in church restorations that valuable historical links had been sacrificed to the preference of the characteristics of some particular period. If additions had to be made to old buildings of various styles, the circumstances would generally point out which of these styles ought to be followed. The architect, however, should not allow individual fancy to prevail too much in selection, but should endeavour to put himself as much as possible in the position of a surviving partner to the designer of the original building, and should think at least as much of his predecessor as of himself. In new creations of his own, carried out in any recognised style, he would by all means advise him, whilst inspired and guided by archæological teaching, not to allow himself to be confined and hampered by it. The new materials and means now available should not but lead them, as years went on, more and more away from the past; but to succeed it must be done, not by revolution, but by evolution. One of the most important considerations at the outset of architectural study was to entertain sound notions respecting materials, not only as regarded strength and durability, but as to their proper employment, and this was especially the case when they considered the number of new materials which were now available. He did not advise the patronage of novelties, but of such as had already won the favour of practical men. In actual building it was well to remember that, whilst studying all reasonable economy, which was a duty in almost every case, sufficient solidity of construction and well-chosen material and a good shape, which generally involved but little, if any, extra cost, were far preferable, and would give more satisfaction both to the employer and the general public than any effect to be obtained by ornament. To give a simple illustration, a plain chimney-stack, surmounting a roof of good thick slating, was far more effective than an elaborately-panelled stack, rising from a covering of flimsy character, of which there was now too much in the market. In the earlier part of this century there was a great abuse of stucco and Roman cement, which were used in situations quite unfit to endure the action of the weather and the test of time. Fluted Corinthian columns, with their base mouldings and capitals and other enrichments, were constantly executed in these materials, and provoked a pasquinade in travesty of the compliment paid to Augustus for having found Rome brick and left it marble:—"Our George he did the same, but did it faster, For he found London brick and left it plaster." That skit, and the stronger artillery used by A. W. N. Pugin in his "Contrasts" and other writings, brought in the desire for more truthful materials. The reaction against stucco, however, was carried to such a degree that it has been dispossessed of even its legitimate field, that of clothing plain brick or rubble walls, for which it was frequently used by the Greeks, the Romans, by the great architects of the Italian revival, and constantly in Mediæval works—for instance, by William of Wykeham—as an external coating of flint walls. Plaster surfaces should, indeed, never be used so as to pretend to be anything different from what they were; they should only be employed when desired to cover rubble or uneven brickwork, and when so treated should not be blocked in imitation of ashlar masonry. For such restricted work as this the architect would have a good argument to offer, drawn both from reason and authority. To the complete oscillation of the pendulum of fashion away from the over-use of stucco he attributed a great mistake which had often been made in church restoration, in which we too frequently found that the rubble walls of the interior had been denuded of their original coating of plaster, a covering which in ancient times was fre-

quently adorned with frescoes, and which might very properly be so treated now, and the walls so exposed exhibit a very forbidding aspect of confused pointing and general untidiness. Everything which had to endure strain and pressure or the searching of the elements should be of better material than stucco, as well as everything that was to show the hand of the artificer in carved or moulded work, which had better be left out altogether than be displayed in external work at any rate, as mere cast repetitions. The objection to the mechanical repetition so disagreeable in plaster enrichments did not apply so strongly in terra-cotta, because in the kiln a certain amount of variety was produced, and, therefore, both on this ground and because of its greater durability it was much freer from objection; but it should be used with greater reserve than it often was, and with more consideration for the fitness of the material with which it was to be associated. It might combine with an exterior otherwise mainly brick with excellent effect as a superior quality of the same nature. The old houses at East Basham, Norfolk, and Sutton Manor, near Ripley, in Surrey, were good examples of this kind. It should not be used in combination with rubble or flint walling, and it was out of place when the general effect was supposed to be masonry, but with terra-cotta simply substituted for stone. But it was in the proper employment of steel and iron where chiefly the new materials demanded the exercise of thought, and this question became every year more prominent. Iron had become admirably useful and was constantly employed as a concealed material; but the time must come before long when for some classes of building it would have to take its own place in architecture; and the best way to meet this requirement might very fitly occupy the thoughts of the rising generation of architects. He did not pretend to have any practical suggestions to offer; he had never had to grapple with the problem. He was inclined to think that the proper treatment of shop fronts would bring about the solution; for there was now a marked contention between the ground storey, where every possible square foot of plate-glass was demanded, and the more usual and quasi-domestic character of the superstructure. Nothing was more dreadful in appearance than the façades which we often saw with a display of solid architecture, where the orders and pedimented windows seemed to rest, as if by magic, upon a surface of plate-glass, occupying the whole breadth of the front at the street level. In this contention the shop-front must carry the day and the old-fashioned form of the upper storeys would have to yield. How this was to be done he did not venture to advise, but it would rest with them to work out the desired result. This they would do by always aiming at using building materials in the most natural way, and then truth of construction would produce a satisfactory result if directed with the intelligence which grew from proper study and a feeling for proportion.

The Institute had received in trust, through the liberality of the Duke of Devonshire, a fine collection of drawings by some of the old masters in architecture. Referring to M. Chedanne's drawings, the President observed that into the very interesting historical and archæological points illustrated in the drawings he did not propose to enter. He wished to call to their attention the wonderful elaboration and refinement of finish in the drawings, and the pains which must have been taken to ascertain and accurately, as well as artistically, delineate so much valuable detail. Their best draughtsmen would be the first to recognise that they in England had nothing comparable to them. Although he did not think that, considering their methods of education and their requirements, they would be justified in urging their students to attempt rivalry with such works as they saw there that night, it was well worth the attention of those who wished to improve their draughtsmanship beyond the utilitarian limit to examine well M. Chedanne's drawings for the sake of their stimulating effect.

Mr. R. PHÉNÉ SPIERS read a summary of M. Chedanne's report to the Academy of Fine Arts, France. M. Chedanne observed that before commencing the work of restoration he had already noted, when measuring the plan, that the axes of the small altars, which formed the chief elements of the interior decoration, and those of the circular niches or apses, formed in the thickness of the wall, were in the same line. That fact gave him an absolute proof that the builder of the edifice was also its decorator. His researches disproved the hypothesis of Piranesi that the greater arch formed part of a series which constituted the outer skin of the cupola. Further examination also disproved the assumption that the dome of the Pantheon was constructed in light porous stone and pottery, and would not be able to carry the bronze flower bosses in the centre of the coffers and on the ribs, as he found bronze cramps built into the solid vault to carry those features. The whole vault was, in fact, built in solid brick, and was supported at its springing by the great vertical arches, which were carried through the thickness of the wall, rising outside to the top of the circular wall of the building. M. Chedanne went on to remark that the removal of some of the bricks from the main vault was facilitated by the cracks already existing there,

and it was not without astonishment that he noted that they were stamped with dies known to be of the time of Hadrian, and of the probable date of 123 A.D. The result of that discovery, which was by far the most important made by M. Chedanne, not only enabled him to decide that the whole of the rotunda was built by Hadrian, but led to a series of researches respecting the famous portico of Agrippa, respecting which M. Chedanne remarked that till within recent times it had always been looked upon as an addition made by Agrippa to shelter the statue of Augustus and his own, which the Emperor forbade him to place in the interior of the temple by the sides of those of the Cæsars. Its composition and plan was regarded as a confirmation of the writings of Dion Cassius, which formed nearly always the starting-point of studies relating to the Pantheon. On careful examination of the construction it was easy to see by the bond of the courses, the projection of cornices, the brick bonding courses, and the setting back of the exterior wall-surface of the circular wall, that the rotunda, with its brick projection and the portico were built at the same time. That which surprised him the most, however, was the absence of any suggestion as to the numerous defects which constituted the clearest proof that the existing portico was a reconstruction long posterior to the age of Augustus. M. Chedanne gave reasons for his hypothesis that the original portico of Agrippa was decastyle.

A vote of thanks was then passed to the French Government for loan of drawings and to M. Chedanne for explaining them. The prizes having been distributed the meeting adjourned.

Bygones.

"Antiquity after a time has the grace of novelty."—HAZLITT.

HALLAM ON THE PROGRESS OF DOMESTIC ARCHITECTURE.

THE qualities by which Henry Hallam was adapted to become a historian of an unique kind were of the judicial sort. As Macaulay said of him, "He sums up with a calm, steady impartiality, turning neither to the right nor to the left, glossing over nothing, exaggerating nothing." At the same time it must be admitted that he was "a hanging judge, the Page or Buller of the high court of literary justice." The remarks on the progress of Domestic architecture in Europe which we publish are as good a sample of Hallam's treatment as any of his investigations of constitutional or literary subjects. He gives the evidence on which he relies and does not attempt to exaggerate its value. He is also impartial in his conclusions. The supposition that Mediæval life was delightful, which was a consequence of the acceptance of Sir Walter Scott's descriptions in his poems and novels, is shown to be only the effect of imagination. But the doctrine of the progress of social life which only a few believed in is upheld. There have been many historians in England, but there is not one of them who attempted to write a summary of the history of architecture which is comparable with the following by Henry Hallam:—

No chapter in the history of national manners would illustrate so well if duly executed the progress of social life as that dedicated to Domestic architecture. The fashions of dress and of amusements are generally capricious and irreducible to rule, but every change in the dwellings of mankind, from the rudest wooden cabin to the stately mansion, has been dictated by some principle of convenience, neatness, comfort or magnificence. Yet this most interesting field of research has been less beaten by our antiquaries than others comparatively barren. I do not pretend to a complete knowledge of what has been written by these learned inquirers, but I can only name one book in which the civil architecture of our ancestors has been sketched, loosely indeed, but with a superior hand, and another in which it is partially noticed. I mean by the first a chapter in the appendix to Dr. Whitaker's "History of Whalley," and by the second Mr. King's Essays on Ancient Castles in the "Archæologia," vols. iv. and vi. Of these I shall proceed to make free use in the following paragraphs.

The most ancient buildings which we can trace in this island after the departure of the Romans were circular towers of no great size, whereof many remain in Scotland, erected either on a natural eminence or on an artificial mound of earth. Such are Conisborough Castle, in Yorkshire, and Castleton, in Derbyshire, built perhaps before the Conquest.* To the lower

chambers of those gloomy keeps there was no admission of light or air, except through long narrow loopholes and an aperture in the roof. Regular windows were made in the upper apartments. Were it not for the vast thickness of the walls, and some marks of attention both to convenience and decoration in these structures, we might be induced to consider them as rather intended for security during the transient inroad of an enemy than for a chieftain's usual residence. They bear a close resemblance, except by their circular form and more insulated situation, to the peels or square towers of three or four storeys which are still found contiguous to ancient mansion houses, themselves far more ancient, in the northern counties, and seem to have been designed for places of refuge.

In course of time the barons who owned these castles began to covet a more comfortable dwelling. The keep was either much enlarged or altogether relinquished as a place of residence except in time of siege, while more convenient apartments were sometimes erected in the tower of entrance over the great gateway which led to the inner ballium or courtyard. Thus at Tunbridge Castle, this part of which is referred by Mr. King to the beginning of the thirteenth century, there was a room, 28 feet by 16, on each side of the gateway; another above of the same dimensions, with an intermediate room over the entrance, and one large apartment on a second floor occupying the whole space and intended for state. The windows in this class of castles were still little better than loopholes on the basement storey, but in the upper rooms often large and beautifully ornamented, though always looking inwards to the court. Edward I. introduced a more splendid and convenient style of castles, containing many habitable towers with communicating apartments. Conway and Carnarvon will be familiar examples. The next innovation was the castle-palace, of which Windsor, if not quite the earliest, is the most magnificent instance. Alnwick, Naworth, Harewood, Spofforth, Kenilworth and Warwick were all built upon this scheme during the fourteenth century, but subsequent enlargements have rendered caution necessary to distinguish their original remains. "The odd mixture," says Mr. King, "of convenience and magnificence, which characterises designs for protection and defence, and with the inconveniences of the former confined plan of a close fortress, is very striking." The provisions for defence became now, however, little more than nugatory; large arched windows like those of cathedrals were introduced into halls, and this change in architecture manifestly bears witness to the cessation of baronial wars, and the increasing love of splendour in the reign of Edward III.

To these succeeded the castellated houses of the fifteenth century, such as Hurstmonceaux, in Sussex, Haddon Hall, in Derbyshire, and the older part of Knowle, in Kent.* They resembled fortified castles in their strong gateways, their turrets and battlements, to erect which a royal license was necessary, but their defensive strength could only have availed against a sudden affray or attempt at forcible dispossession. They were always built round one or two courtyards, the circumference of the first, when there were two, being occupied by the offices and servants' rooms, that of the second by the state apartments. Regular quadrangular houses, not castellated, were sometimes built during the same age, and under Henry VII. became universal in the superior style of Domestic architecture. The quadrangular form, as well from security and convenience as from imitation of conventual houses, which were always constructed upon that model, was generally preferred; even where the dwelling-house, as indeed was usual, only took up one side of the enclosure, and the remaining three contained the offices, stables and farm-buildings, with walls of communication. Several very old parsonages appear to have been built in this manner. It is, however, very difficult to discover any fragments of houses inhabited by the gentry before the reign, at soonest, of Edward III., or even to trace them by engravings in the older topographical works, not only from the dilapidations of time, but because very few considerable mansions had been erected by that class. A great part of England affords no stone fit for building, and the vast, though unfortunately not inexhaustible, resources of her oak forests were easily applied to less durable and magnificent structures. A frame of massive timber, independent of walls and resembling the inverted hull of a large ship, formed the skeleton, as it were, of an ancient hall; the principal beams springing from the ground naturally curved, and formed a Gothic arch overhead. The intervals of these were filled up with horizontal planks, but in the earlier buildings, at least in some districts, no part

a royal residence, which it certainly never was after the Conquest. But if the engravings of the decorative parts in *Archæologia* are not remarkably inaccurate the architecture is too elegant for the Danes, much more for the unconverted Saxons. Both these castles are enclosed by a court or ballium, with a fortified entrance, like those erected by the Normans.

* The ruins of Hurstmonceaux are, I believe, tolerably authentic remains of Henry VI.'s age, but a modern antiquary asserts that only one of the courts at Haddon Hall is of the fifteenth century.—Lysons's *Derbyshire*.

* Mr. Lysons refers Castleton to the age of William the Conqueror, but without giving any reasons. Mr. King had satisfied himself that it was built during the Heptarchy, and even before the conversion of the Saxons to Christianity, but in this he gave the reins, as usual, to his imagination, which as much exceeded his learning as the latter did his judgment. Conisborough should seem by the name to have been

of the walls was of stone. Stone houses are, however, mentioned as belonging to citizens of London, even in the reign of Henry II., and, though not often perhaps regularly-hewn stones, yet those scattered over the soil, or dug from flint quarries, bound together with a very strong and durable cement, were employed in the construction of manorial houses, especially in the western counties, and other parts where that material is easily procured.* Gradually, even in timber buildings, the intervals of the main beams, which now became perpendicular, not throwing off their curved springers till they reached a considerable height, were occupied by stone walls, or, where stone was expensive, by mortar or plaster, intersected by horizontal or diagonal beams, grooved into the principal piers. This mode of building continued for a long time, and is still familiar to our eyes in the older streets of the Metropolis and other towns, and in many parts of the country.† Early in the fourteenth century the art of building with brick, which had been lost since the Roman dominion, was introduced, probably from Flanders. Though several edifices of that age are constructed with this material, it did not come into general use till the reign of Henry VI. Many considerable houses, as well as public buildings, were erected with bricks during his reign and that of Edward IV., chiefly in the eastern counties, where the deficiency in stone was most experienced. Few, if any, brick mansion houses of the fifteenth century exist, except in a dilapidated state; but Queen's College and Clare Hall at Cambridge, and part of Eton College, are subsisting witnesses to the durability of the material as it was then employed.

It is an error to suppose that the English gentry were lodged in stately or even in well-sized houses. Generally speaking, their dwellings were almost as inferior to those of their descendants in capacity as they were in convenience. The usual arrangement consisted of an entrance-passage running through the house, with a hall on one side, a parlour beyond, and one or two chambers above, and on the opposite side a kitchen, pantry and other offices.‡ Such was the ordinary manor-house of the fifteenth and sixteenth centuries, as appears not only from the documents and engravings, but, as to the latter period, from the buildings themselves, sometimes, though not very frequently, occupied by families of consideration, more often converted into farmhouses or distinct tenements. Larger structures were erected by men of great estates during the reigns of Henry VI. and Edward IV., but very few can be traced higher; and such has been the effect of time, still more through the advance or decline of families and the progress of architectural improvement than the natural decay of these buildings, that I should conceive it difficult to name a house in England still inhabited by a gentleman, and not belonging to the order of castles, the principal apartments of which are older than the reign of Henry VII. The instances at least must be extremely few.§

France by no means appears to have made a greater progress than our own country in Domestic architecture. Except fortified castles, I do not find in the work of a very miscellaneous, but apparently diligent writer,|| any considerable dwellings mentioned before the reign of Charles VII., and very few of so early a date.¶ Jacques Cœur, a famous merchant,

* Harrison says that few of the houses of the commonalty, except here and there in the west country towns, were made of stone. This was about 1570.

† "The ancient manours and houses of our gentlemen," says Harrison, "are yet, and for the most part, of strong timber, in framing whereof our carpenters have been and are worthily preferred before those of like science among all other nations. Howbeit such as are lately builded are either of brick or hard stone, or both."

‡ In Strutt's *View of Manners* we have an inventory of furniture in the house of Mr. Richard Fermor, ancestor of the Earl of Pomfret, at Easton, in Northamptonshire, and another in that of Sir Adrian Foskew. Both these houses appear to have been of the dimensions and arrangement mentioned. And even in houses of a more ample extent, the bisection of the ground-plot by an entrance-passage was, I believe, universal, and is a proof of antiquity. Haddon Hall and Penshurst still display this ancient arrangement, which has been altered in some old houses. About the reign of James I., or perhaps a little sooner, architects began to perceive the additional grandeur of entering the great hall at once.

§ Single rooms, windows, doorways, &c., of an earlier date may perhaps not unfrequently be found; but such instances are always to be verified by their intrinsic evidence, not by the tradition of the place. The most remarkable fragment of early building which I have anywhere found mentioned is at a house in Berkshire, called Appleton, where there exists a sort of prodigy, an entrance-passage with circular arches in the Saxon style, which must probably be as old as the reign of Henry II. No other private house in England, as I conceive, can boast of such a monument of antiquity.—Lysons's *Berkshire*.

|| It is to be regretted that Le Grand d'Aussy never completed that part of his *Vie privée des Français* which was to have comprehended the history of civil architecture. Villaret has noticed its state about 1380.

¶ Chenonceaux, in Touraine, was built by a nephew of Chancellor Duprat; Gaillon, in the Department of Eure, by Cardinal Amboise;

unjustly persecuted by that prince, had a handsome house at Paris, as well as another at Beaumont-sur-Oise. It is obvious that the long calamities which France endured before the expulsion of the English must have retarded this eminent branch of national improvement.

Even in Italy, where from the size of her cities and social refinements of her inhabitants, greater elegance and splendour in building were justly to be expected, the Domestic architecture of the Middle Ages did not attain any perfection. In several towns the houses were covered with thatch, and suffered consequently from destructive fires. Costanzo, a Neapolitan historian near the end of the sixteenth century, remarks the change of manners that had occurred since the reign of Joanna II., 150 years before. The great families under the queen expended all their wealth on their retainers, and placed their chief pride in bringing them into the field. They were ill-lodged, not sumptuously clothed, nor luxurious in their tables. The house of Caracciolo, high steward of that princess, one of the most powerful subjects that ever existed, having fallen into the hands of persons incomparably below his station, had been enlarged by them, as insufficient for their accommodation. If such were the case in the city of Naples so late as the beginning of the fifteenth century, we may guess how mean were the habitations in less polished parts of Europe.

The two most essential improvements in architecture during this period, one of which had been missed by the sagacity of Greece and Rome, were chimneys and glass windows. Nothing apparently can be more simple than the former; yet the wisdom of ancient times had been content to let the smoke escape by an aperture in the centre of the roof; and a discovery, of which Vitruvius had not a glimpse, was made perhaps in this country by some forgotten semi-barbarian. About the middle of the fourteenth century the use of chimneys is distinctly mentioned in England and in Italy; but they are found in several of our castles which bear a much older date.* This country seems to have lost very early the art of making glass, which was preserved in France, whence artificers were brought into England to furnish the windows in some new churches in the seventh century. It is said that in the reign of Henry III. a few ecclesiastical buildings had glazed windows. Suger, however, a century before, had adorned his great work, the abbey of St. Denis, with windows not only glazed but painted, and I presume that other churches of the same class, both in France and England, especially after the lancet-shaped window had yielded to one of ampler dimensions, were generally decorated in a similar manner. Yet glass is said not to have been employed in the Domestic architecture of France before the fourteenth century, and its introduction into England was probably by no means earlier. Nor indeed did it come into general use during the period of the Middle Ages. Glazed windows were considered as movable furniture and probably bore a high price. When the Earls of Northumberland as late as the reign of Elizabeth left Alnwick Castle, the windows were taken out of their frames and carefully laid by.†

But if the Domestic buildings of the fifteenth century would not seem very spacious or convenient at present, far less would this luxurious generation be content with their internal accommodations. A gentleman's house containing three or four beds was extraordinarily well provided; few probably had more than two. The walls were commonly bare, without wainscot or even plaster, except that some great houses were furnished with hangings, and that perhaps hardly so soon as the reign of Edward IV. It is unnecessary to add that neither libraries of

both at the beginning of the sixteenth century. These are now considered, in their ruins, as among the most ancient houses in France. A work by Du Cerceau gives accurate engravings of thirty houses; but, with one or two exceptions, they seem all to have been built in the sixteenth century. Even in that age defence was naturally an object in constructing a French mansion house; and where defence is to be regarded, splendour and convenience must give way. The name of château was not retained without meaning.

* Beckman's *History of Inventions*, a work of very great research, cannot trace any explicit mention of chimneys beyond the writings of John Villani, wherein, however, they are not noticed as a new invention. Piers Plowman, a few years later than Villani, speaks of a "chambre with a chimney," in which rich men usually dined. But in the account-book of Bolton Abbey, under the year 1311, there is a charge "pro faciendo camino" in the rectory-house of Gargrave. This may, I think, have been only an iron stove or fire-pan, though Dr. W. without hesitation translates it a chimney. However, Mr. King, in his observations on ancient castles, *Archæologia*, and Mr. Strutt, describe chimneys in castles of a very old construction. That at Conisborough, in Yorkshire, is peculiarly worthy of attention, and carries back this important invention to a remote antiquity. Chimneys are still more modern in France; and seem, according to Paulmy, to have come into common use since the middle of the seventeenth century. "Jadis nos pères n'avoient qu'un unique chauffoir, qui étoit commun à toute une famille, et quelquefois à plusieurs," t. iii. p. 133. In another place, however, he says:—"Il paraît que les tuyaux de cheminées étoient déjà très en usage en France."

† Bishop Percy says, on the authority of Harrison, that glass was not commonly used in the reign of Henry VIII.

books nor pictures could have found a place among furniture. Silver plate was very rare and hardly used for the table. A few inventories of furniture that still remain exhibit a miserable deficiency.* And this was incomparably greater in private gentlemen's houses than among citizens, and especially foreign merchants. We have an inventory of the goods belonging to Contarini, a rich Venetian trader, at his house in St. Botolph's Lane, A.D. 1481. There appear to have been not less than ten beds, and glass windows are specially noticed as movable furniture. No mention, however, is made of chairs or looking-glasses.† If we compare this account, however trifling in our estimation, with a similar inventory of furniture in Skipton Castle, the great honour of the Earls of Cumberland, and among the most splendid mansions of the north, not at the same period—for I have not found any inventory of a nobleman's furniture so ancient—but in 1572, after almost a century of continual improvement, we shall be astonished at the inferior provision of the baronial residence. There were not more than seven or eight beds in this great castle, nor had any of the chambers either chairs, glasses or carpets.‡ It is in this sense, probably, that we must understand Æneas Sylvius, if he meant anything more than to express a traveller's discontent, when he declares that the kings of Scotland would rejoice to be as well lodged as the second class of citizens at Nuremberg.§ Few burghers of that town had mansions, I presume, equal to the palaces of Dunfermline or Stirling, but it is not unlikely that they were better furnished.

In the construction of farmhouses and cottages, especially the latter, there have probably been fewer changes, and those it would be more difficult to follow. No building of this class can be supposed to exist of the antiquity to which the present work is confined; and I do not know that we have any document as to the inferior architecture of England so valuable as one which M. de Paulmy has quoted for that of France, though perhaps more strictly applicable to Italy, an illuminated manuscript of the fourteenth century, being a translation of Crescentio's work on agriculture, illustrating the customs and, among other things, the habitations of the agricultural class. According to Paulmy, there is no other difference between an ancient and a modern farmhouse than arises from the introduction of tiled roofs. In the original work of Crescentio, a native of Bologna, who composed this treatise on rural affairs about the year 1300, an Italian farmhouse, when built, at least according to his plan, appears to have been commodious both in size and arrangement.|| Cottages in England seem to have generally consisted of a single room without division of storeys. Chimneys were unknown in such dwellings till the early part of Elizabeth's reign, when a very rapid and sensible improvement took place in the comforts of our yeomanry and cottagers.¶

* See some curious valuations of furniture and stock in trade at Colchester in 1296 and 1301. A carpenter's stock was valued at a shilling, and consisted of five tools. Other tradesmen were almost as poor; but a tanner's stock, if there is no mistake, was worth 9*l.* 7*s.* 10*d.*, more than ten times any other. Tanners were principal tradesmen, the chief part of dress being made of leather. A few silver cups and spoons are the only articles of plate; and as the former are valued but at one or two shillings, they had, I suppose, but a little silver on the rim.

† Nicholl's *Illustrations*. Among several interesting facts of the same class, we have another inventory of the goods of "John Port, late the king's servant," who died about 1524. He seems to have been a man of some consideration, and probably a merchant. The house consisted of a hall, parlour, buttery and kitchen with two chambers, and one smaller on the floor above; a napery or linen-room and three garrets, besides a shop, which was probably detached. There were five bedsteads in the house, and on the whole a great deal of furniture for those times, much more than I have seen in any other inventory. His plate is valued at 94*l.*, his jewels at 23*l.*, his funeral expenses come to 73*l.* 6*s.* 8*d.*

‡ A better notion of the accommodations usual in the rank immediately below may be collected from two inventories published by Strutt, one of Mr. Fermor's house at Easton, the other Sir Adrian Foscawe's. I have mentioned the size of these gentlemen's houses already. In the former the parlour had wainscot, a table and a few chairs; the chambers above had two best beds and there was one servant's bed; but the inferior servants had only mattresses on the floor. The best chambers had window-shutters and curtains. Mr. Fermor, being a merchant, was probably better supplied than the neighbouring gentry. His plate, however, consisted only of sixteen spoons and a few goblets and ale-pots. Sir Adrian Foscawe's opulence appears to have been greater; he had a service of silver plate and his parlour was furnished with hangings. This was in 1539. It is not to be imagined that a knight of the shire a hundred years before would have rivalled even this scanty provision of movables. These details, trifling as they may appear, are absolutely necessary in order to give an idea with some precision of a state of national wealth so totally different from the present.

§ "Cuperent tam egregie Scotorum reges quam mediocres Nurembergæ cives habitare." Æn. Sylv. apud Schmidt, *Hist. des Allemands*.

|| Crescentius, in *Commod. Rurali*. This old edition contains many coarse woodcuts, possibly taken from the illuminations which Paulmy found in his manuscript.

¶ Chimneys were not used in the farmhouses of Cheshire till within forty years of the publication of King's *Vale Royal*, 1636.

It must be remembered that I have introduced this disadvantageous representation of civil architecture as a proof of general poverty and backwardness in the refinements of life. Considered in its higher departments, that art is the principal boast of the Middle Ages. The common buildings, especially those of a public kind, were constructed with skill and attention to durability. The castellated style displays these qualities in greater perfection; the means are well adapted to their objects, and its imposing grandeur, though chiefly resulting, no doubt, from massiveness and historical association, sometimes indicates a degree of architectural genius in the conception. But the most remarkable works of this are the religious edifices erected in the twelfth and three following centuries. These structures, uniting sublimity in general composition with the beauties of variety and form, intricacy of parts, skilful, or at least fortunate, effects of shadow and light, and in some instances with extraordinary mechanical science, are naturally apt to lead those antiquaries who are most conversant with them into too partial estimates of the times wherein they were founded. They certainly are accustomed to behold the fairest side of the picture. It was the favourite and most honourable employment of ecclesiastical wealth to erect, to enlarge, to repair, to decorate cathedral and conventual churches. An immense capital must have been expended upon these buildings in England between the Conquest and the Reformation. And it is pleasing to observe how the seeds of genius, hidden as it were under the frost of that dreary winter, began to bud to the first sunshine of encouragement. In the darkest period of the Middle Ages, especially after the Scandinavian incursions into France and England, ecclesiastical architecture, though always far more advanced than any other art, bespoke the rudeness and poverty of the times. It began towards the latter part of the eleventh century, when tranquillity, at least as to former enemies, was restored, and some degree of learning reappeared, to assume a more noble appearance. The Anglo-Norman cathedrals were perhaps as much distinguished above other works of man in their own age as the more splendid edifices of a later period. The science manifested in them is not, however, very great; and their style, though by no means destitute of lesser beauties, is upon the whole an awkward imitation of Roman architecture, or perhaps more immediately of the Saracenic buildings in Spain and those of the lower Greek empire.* But about the middle of the twelfth century this manner began to give place to what is improperly denominated the Gothic architecture,† of which the Pointed arch, formed by the segments of two intersecting semicircles, struck from points equidistant from the centre of a common diameter, has been deemed the essential characteristic. We are not concerned at present to inquire whether this style originated in France or Germany, Italy or England, since it

The fire was in the midst of the house, against a hob of clay, and the oxen lived under the same roof.

* The Saracenic architecture was once conceived to have been the parent of the Gothic. But the Pointed arch does not occur, I believe, in any Moorish buildings; while the great mosque of Cordova, built in the eighth century, resembles, except by its superior beauty and magnificence, one of our oldest cathedrals—the nave of Gloucester, for example, or Durham. Even the vaulting is similar, and seems to indicate some imitation, though perhaps of a common model. Compare *Archæologia*, vol. xvii. plates 1 and 2, with Murphy's *Arabian Antiquities*, plate 5. The pillars, indeed, at Cordova are of the Corinthian order, perfectly executed, if we may trust the engraving, and the work, I presume, of Christian architects; while those of our Anglo-Norman cathedrals are generally an imitation of the Tuscan shaft, the builders not venturing to trust their roofs to a more slender support, though Corinthian foliage is common in the capitals, especially those of smaller ornamental columns. In fact, the Roman architecture is universally acknowledged to have produced what we call the Saxon or Norman; but it is remarkable that it should have been adopted, with no variation but that of the singular horseshoe arch, by the Moors of Spain. The Gothic, or Pointed arch, though very uncommon in the genuine Saracenic of Spain and the Levant, may be found in some prints from Eastern buildings, and is particularly striking in the façade of the great mosque at Lucknow, in Salt's designs for Lord Valentia's *Travels*. The Pointed arch buildings in the Holy Land have all been traced to the age of the Crusades. Some arches, if they deserve the name, that have been referred to this class are not Pointed by their construction, but rendered such by cutting off and hollowing the projections of horizontal stones.

† Gibbon has asserted, what might justify this appellation, that "the image of Theodoric's palace at Verona, still extant on a coin, represents the oldest and most authentic model of Gothic architecture." For this he refers to Maffei, *Verona Illustrata*, where we find an engraving, not indeed of a coin, but of a seal, the building represented on which is in a totally dissimilar style. The following passage in Cassiodorus, for which I am indebted to M. Ginguené, would be more to the purpose. "Quid dicamus columnarum junceam proceritatem? moles illas sublimissimas fabricarum quasi quibusdam erectis hastilibus contineri." These columns of reedy slenderness, so well described by "juncea proceritas," are said to be found in the cathedral of Monreale in Sicily, built in the eighth century. They are not, however, sufficient to justify the denomination of Gothic, which is usually confined to the Pointed arch style.

was certainly almost simultaneous in all these countries,* nor from what source it was derived, a question of no small difficulty. I would only venture to remark that whatever may be the origin of the Pointed arch, for which there is more than one mode of accounting, we must perceive a very Oriental character in the vast profusion of ornament, especially on the exterior surface, which is as distinguishing a mark of Gothic buildings as their arches, and contributes in an eminent degree both to their beauties and to their defects. This, indeed, is rather applicable to the later than the earlier stage of architecture, and rather to continental than English churches. Amiens is in a far more florid style than Salisbury, though a contemporary structure. The Gothic species of architecture is thought by some to have reached its perfection, considered as an object of taste, by the middle of the fourteenth century, or at least to have lost something of its excellence by the corresponding part of the next age, an effect of its early and rapid cultivation, since arts appear to have, like individuals, their natural progress and decay. Yet this seems, if true at all, only applicable to England, since the cathedrals of Cologne and Milan, perhaps the most distinguished monuments of this architecture, are both of the fifteenth century. The mechanical execution, at least, continued to improve, and is so far beyond the apparent intellectual powers of those times that some have ascribed the principal ecclesiastical structures to the fraternity of freemasons, depositaries of a concealed and traditionary science. There is, probably, some ground for this opinion; and the earlier archives of that mysterious association, if they existed, might illustrate the progress of Gothic architecture, and perhaps reveal its origin. The remarkable change into this new style that was almost contemporaneous in every part of Europe cannot be explained by any local circumstances, or the capricious taste of a single nation.†

THE PROPOSED SITE FOR CHRIST'S HOSPITAL AT HORSHAM.

THE Master of Marlborough College, as a member of the Council of Almoners of Christ's Hospital who supported the resolution passed last December to build the new Boys' School at Horsham, has published the following statement in answer to an article which appeared in the *Times* :—

Many letters and communications, most of them anonymous, have appeared during the last few months in the *Times* and other papers, condemning the policy of removing the school to the Horsham estate.

The advocates of this policy have hitherto not attempted to answer these criticisms, in spite of their frequent unfairness and inaccuracy, and so long as the removal to Horsham was still under discussion among the governing body there may have been sufficient reason for abstaining from an appeal to public opinion.

But the Council at their last meeting decided, *nem. con.*, to "place the building for the new Boys' School on the Horsham estate;" and on December 27 there appeared in the *Times*

* The famous Abbot Suger, Minister of Louis VI., rebuilt St. Denis about 1140. The cathedral of Laon is said to have been dedicated in 1114. I do not know in what style the latter of these churches is built, but the former is, or rather was, Gothic. Notre Dame at Paris was begun soon after the middle of the twelfth century, and completed under St. Louis. — *Mélanges tirés d'une grande bibliothèque*, t. xxxi. p. 108. In England, the earliest specimen I have seen of Pointed arches is in a print of St. Botolph's Priory at Colchester, said by Strutt to have been built in 1110. — *View of Manners*, vol. i. plate 30. These are apertures formed by excavating the space contained by the intersection of semicircular or Saxon arches, which are perpetually disposed, by way of ornament, on the outer as well as inner surface of old churches, so as to cut each other, and consequently to produce the figure of a Gothic church, and if there is no mistake in the date, they are probably among the most ancient of that style in Europe. Those at the church of St. Cross, near Winchester, are of the reign of Stephen; and, generally speaking, the Pointed style, especially in vaulting, the most important object in the construction of a building, is not considered older than Henry II. The nave of Canterbury Cathedral, of the erection of which by a French architect about 1176 we have a full account in Gervase, and the Temple Church, dedicated in 1183, are the most ancient English buildings altogether in the Gothic manner.

† The curious subject of freemasonry has unfortunately been treated only by panegyrists or calumniators, both equally mendacious. I do not wish to pry into the mysteries of the craft, but it would be interesting to know more of their history during the period when they were literally architects. They are charged by an Act of Parliament, 3 Henry VI., with fixing the price of their labour in their annual chapters, contrary to the statute of labourers, and such chapters are consequently prohibited. This is their first persecution; they have since undergone others, and are perhaps reserved for still more. It is remarkable that masons were never legally incorporated like other traders, their bond of union being stronger than any charter.

an article on this question, mainly based on the report of Mr. Rogers Field, which is quoted at great length.

The object of the article is plainly shown by the choice of passages from the report, and by the summary of objections at the end. The writer wishes to convince the public that the balance of evidence and argument is on the side of those "who have openly declared war against the utilisation of the site purchased by the Council of Almoners for Christ's Hospital at Horsham."

Plainly the time has now come when the policy of the Council should be publicly vindicated, else it may be supposed, even by their friends, that their decision is indefensible, or at least overborne by stronger arguments.

The objections to their decision are chiefly based on statements in Mr. Rogers Field's report, which are ingeniously marshalled in such a way as to imply that Mr. Field is absolutely hostile to the proposal to build at Horsham.

It will then be convenient to consider the real import of these statements, and to show that neither Mr. Field's report nor the other facts relating to the estate justify a verdict adverse to the decision of the Council.

Mr. Field's able and exhaustive report deals, as the *Times* article shows, with three main subjects :—

1. The Water-supply.—His careful investigation proved conclusively that the existing water-supply was insufficient for the needs of a large school. The Council, therefore, in accordance with his advice, have had a boring sunk at the point suggested by him to the depth of about 350 feet. This boring is not yet completed, but already it has produced a supply of water at the rate of forty gallons a minute, and an analysis of this water has proved that its quality is excellent in all respects.

But before this boring was commenced the Council had ascertained that, if it should fail to produce a sufficient supply of water, the waterworks of the town of Horsham would be fully able to supply the school with the excellent water there obtained from the lower strata of the Tunbridge Wells sand. All the quotations from Mr. Field's report about the water-supply which he investigated have, therefore, ceased to be relevant.

2. The second point dealt with by Mr. Field is the disposal of sewage from the school buildings. He makes suggestions which the Council would be prepared to adopt failing a still better plan which is under consideration.

In this part of the report reference is made to the "slight and occasional flooding of the lowest portion of the ground."

As this reference has furnished a weapon to objectors, it should be clearly understood that the spot in question is a small corner close to the river Arun, on the extreme edge of the estate, which consists in the main of "rising ground commanding wide and distant views" (see statement of the Council), or, as Dr. Kelly says, of "gentle slopes of large extent, freely exposed to the air and sun."

3. The Nature of the Soil.—Even a cursory examination of Mr. Field's report shows that he distinguishes between the "top soil" (to the depth of 2 feet or more, of which he gives no analysis or particulars) and the "subsoil," which is shown by analysis to be clay mingled with varying proportions of sand. This distinction is of primary importance in its bearing on the fitness of the estate for a school.

In the top soil, whatever be the cause (such as tillage, the work of earthworms, &c.), the sand appears to have come to the surface; at any rate the proportion of sand is very considerable. This top soil corresponds accurately to the account of it quoted by the Council from the report of Mr. J. W. Penfold, the surveyor employed by the Charity Commissioners. "It is a fairly light soil, working with a pair-horse plough." The present tenants are tilling it in this way, and during the whole of the Governors' tenancy a flock of from 300 to 400 breeding ewes has been kept without foot-rot or other maladies incidental to wet land.

Further, Mr. Aston Webb and Mr. Ingress Bell, when preparing for competition the designs ultimately chosen by the Council, considered very carefully the nature of the site selected for the buildings and playgrounds of the school. They were assisted in this by Mr. Henry Milner, who is an expert in such questions. They assured the building committee that they were well satisfied with the site, and that with shallow surface drainage of the part selected for the buildings and playgrounds, costing about 10*l.* an acre, the ground would be perfectly well suited for all the purposes of a large school.

Similar assurance is derived from the experience of a neighbouring landowner whose estate has been dealt with in this manner.

The article in the *Times* next dwells upon the report of Dr. Kelly, the Medical Officer of Health for West Sussex and Professor of Hygiene at King's College, London. And again by the choice of passages for quotation it deals with this report in such a way as to disguise or obscure the fact that it is distinctly and strongly in favour of the healthiness of the new site, particularly in regard to scarlatina and diphtheria, the diseases most dreaded by those who have charge of schools.

Dr. Kelly says:—"The facts I have collected over a long term of years relating to the health of persons dwelling on this area show that the rate of mortality is low and the incidence of disease moderate. I conclude, from a consideration of all the facts, that the estate is situated in a healthy spot, and that it is suitable, as explained above, for the purposes of a large school."

It remains to advert briefly to some other objections brought forward in the *Times* article and by other opponents.

(a) The distance from London (37 miles). The facts are as follows:—Before the site was purchased the London and Brighton Company agreed to construct a station on the estate, which is already traversed by their line to Portsmouth, and to convey third-class passengers to this station at a fare of 2s. 6d. for the return journey. This station, within three minutes' walk from the school buildings, would be reached in about 1¼ hours by passengers starting from Victoria or London Bridge. No expense for cabs or transport of luggage would be incurred on arrival.

It would not be easy to match an arrangement so convenient and economical as this; subject to the necessary condition that the school (which is entirely for boarders) should be removed completely away from the rapidly-growing circle of suburban London.

(b) The high price, "55,000*l.*," paid for the estate in spite of its "bleak situation and undeveloped character."

Those who are acquainted with the climatic conditions of some of the most flourishing public schools will simply smile at remarks about the bleakness of a site about 180 feet above the sea-level, and in the same latitude as Folkestone, Godalming and Taunton.

Those who speak of its undeveloped character ignore the fact that it is intersected by several good and well-planned private roads; that there are upon the Stammerham estate a good dwelling-house and twenty-seven substantial cottages, so situated as to be convenient for some of the many outdoor servants and workmen of a large school; and the central buildings of the Aylesbury Dairy Company, constructed at great cost, can be easily and inexpensively adapted for laundry, bakery stores, gymnasium, workshops and other necessary appliances of a school. And one admirable feature of the plans selected by the Council is that the architects have proposed so to utilise these buildings that a very considerable expenditure will be saved which on an "undeveloped" site would have been unavoidable.

These particulars apply to the Stammerham estate of 1,020 acres, purchased at a cost of 47,500*l.*—considerably less than was expended on buildings and improvements by the last owners.

Adjoining Stammerham the Council bought 70 acres of land, in which is the source of a spring that supplies the stream and lake in the grounds of Stammerham; there is also a large dwelling-house which can be turned to good account. This property was purchased for 5,500*l.*

If these facts are fairly considered, it will be found that the Council, in their purchase of the Horsham estate, have shown a due regard for economy.

Moreover, it is quite certain that, so soon as the school has been established on the estate, a demand will begin to arise for such portions of the 1,100 acres as may not be needed, and that the enhanced value of such land will go far to recoup the cost of the original purchase.

Lastly it must be borne in mind that the Council are not wantonly engaging in the enterprise of removing the school from London. They are appointed for the purpose of carrying into effect the provisions of a scheme framed by the Charity Commissioners, and approved by Parliament, in spite of several attempts to defeat it. Of this scheme the removal of the school from London is an essential feature.

EDINBURGH ARCHITECTURAL ASSOCIATION.

At the meeting of this Association a paper by the Rev. R. Scott Mylne, of London, author of "The Master Masons to the Crown of Scotland," was read on "The Architecture of Bologna and North-Eastern Italy." After glancing briefly at the history of the province of Bologna, Mr. Mylne said every traveller had heard of the leaning towers of the city of that name, and everyone went to see them. Nobody knew exactly why they were built, or what precise purpose they were intended to serve, and, although extremely curious, neither possessed architectural merit like the famous marble leaning tower of Pisa. The numerous arcades formed the most interesting architectural feature of the quaint Mediaeval town of Bologna. Marble being scarce in the district, terra-cotta was frequently used for decorative purposes with much taste and skill. The capacious font of the church of St. Marie dei Servi was one of the most remarkable examples of this kind. The long rows of slender marble columns formed an elegant kind of arcade, and in front of the western façade formed a charming little quadrangle. The actual beauty of effect, however, was somewhat

marred by the unfinished state of the main portion of the sacred edifice. In the church of St. Bartholomew there was also a very well designed portico carved in stone by Lombard sculptors in the sixteenth century, from the beautiful designs of Andrea de Formigine, executed A.D. 1530. In the same way many of the spacious residences of the old nobility presented magnificent specimens of Lombard and Renaissance architecture. The street fronts were often very noble, while the gateways, courtyards, staircases and colonnades provided capital examples of detailed design. The beautiful private residence of highest merit in the whole city was the Palazzo Bevilacqua. The façade to the main road was surmounted by a handsome cornice, and each separate stone in the wall was cut in the shape of a diamond with great care and of set purpose. On entering the courtyard the first impression was very pleasing; the symmetry was perfect, and the eye found repose in the gratified sense of true proportion. Delicacy and elegance of design, combined with due subordination of all the different portions of the entire structure, was the principal characteristic of this beautiful building. In the centre of the courtyard was a single ornament, a slender marble column supporting a finely-carved bear, from whose open mouth the whole establishment was supplied with pure water. In the great hall on the upper floor sufficient space was found to assemble the famous Council of Trent in A.D. 1547. Though there were other palaces in Bologna of larger dimensions than the Bevilacqua, and often possessing some particularly fine details, none as a whole excelled in merit that particular residence, which was a typical example of Bolognese skill. Was not the due sense of proportion there so well exhibited just the very thing so often lacking in many fine modern buildings? Some of the fine houses in Bologna were chiefly noticeable for the interesting capitals of the columns on their open arcades towards the streets. The oldest church of Bologna was St. Stephen, and consisted of seven churches of different dates united in one. More than a thousand years divided the most ancient and the most modern masonry, and everywhere archæological treasures abounded. But upon the whole St. Dominic was the most interesting church in the town, because it contained the marble shrine of the famous saint who founded the great monastic order of the Friars Preachers. As a work of art of the highest merit, Ruskin, Lord Lindsay, and other eminent writers devoted much space to a full description of these admirable sculptures. In the remaining part of his paper Mr. Mylne dealt with other great monuments of architecture in the north-eastern portion of Italy, more especially for purposes of comparison. The paper, which was read by Mr. Thomas Ross, was illustrated by a series of photographs. At the close the hearty thanks of the Association were awarded to Mr. Mylne, Mr. W. W. Robertson presided.

GENERAL.

Mr. Matthew Wallace, of the Albion Iron Company, was on Wednesday last sworn in as Justice of the Peace for the County of London, before Sir Peter Edlin, Q.C., at the Middlesex Sessions, Clerkenwell.

Mr. J. Cheaton Parr has given to the Corporation of Warrington a large hall he has had erected in the centre of the town. The hall has been built at a cost of over 6,000*l.*, and will seat nearly two thousand people.

The Surveyors' Institution meet on Monday the 21st inst., when a paper will be read by Mr. H. Blackburn, Fellow, on "The London Building Act, 1894."

The Members of the Police Fire Brigade, Wolverhampton, have resigned. A memorial, it is stated, was submitted to be put before the Watch Committee, but no information as to whether the Watch Committee was forthcoming, and it is considered that at the very least some reply should have been made to the men. Those who are daily prepared to risk their own lives for the public safety deserve better treatment.

The Llandudno Eisteddfod Committee having asked Mr. Ruskin to allow portions of his works to be translated in competition, Mr. Ruskin has acknowledged the implied compliment, but points out that he has always felt extremely indisposed towards translations from his works, and it would, perhaps, be hardly fair to persons to whom he has refused permission to translate into French and German if he were now to sanction translations into Welsh.

The Current Number of the *Quarterly* contains an article tracing the history and progress of the great Ordnance Survey. It is stated that the total cost of the survey, including the triangulation, primary, secondary and tertiary, levelling, surveying, drawing, engraving, publishing, and all necessary indexes, has been between 50*l.* and 51*l.* per square mile, or about 1*s.* 8*d.* an acre. This includes an enormous area of "town plans" on a scale of 1-500, which cost on the average from 1*s.* to 2*s.* per acre. It also includes the whole cost of the 1-inch topographical map and the smaller scales, with which the foreign cadastral surveys have had nothing whatever to do. The normal cost of the 1-2500 survey is about 1*s.* per acre.

The Architect.

THE WEEK.

It is with much regret we record the death at Lancaster, on Wednesday, of EDWARD GRAHAM PALEY, an architect whose reputation for ecclesiastical buildings had extended throughout England. The names of the firms of SHARPE & PALEY, PALEY & AUSTIN, and PALEY, AUSTIN & PALEY are intimately associated with the history of modern Gothic architecture. EDWARD GRAHAM PALEY, who was born in the Vicarage of Easingwold, near York, seventy-two years ago, belonged to a family that had gained reputation. His grandfather was the renowned Archdeacon PALEY, whose books hold their own amidst all the variations of the theories of theology and ethics. His brother, F. A. PALEY, was one of the best editors of Greek and Roman Classics that this century has seen, and was, moreover, a writer who helped to make Gothic popular, especially among religious people. EDWARD PALEY was placed as a pupil with the late EDMUND SHARPE, but beyond initiation into routine we doubt if he gained much. With all his versatility, which was amazing, Mr. SHARPE was not an artist, while EDWARD PALEY was so-endowed by nature. Many of his churches have the spirit of Mediæval times, and in the country often impart a charm to a landscape. The number of churches designed in the Lancaster offices was incredible. In that ancient town Mr. PALEY was a notability, and respected as a man who had added to its reputation. A testimony to his position was given when the Roman Catholics commissioned him to design their large church in Lancaster. He filled several public offices with advantage to the people, and although of late Mr. PALEY was not so often before the public as formerly, his loss will be deplored.

THANKS to the generous munificence of its sons, Paisley is becoming rich in public buildings which have great architectural merit. Among them the Clark Town Hall, the Public Library and Museum, the John Neilson Institution and the Thomas Coats Memorial Church stand out conspicuous. Other three large public buildings will soon be in the course of erection, all of them in the main gifts, namely, a new infirmary, a new grammar school and a technical college. The last mentioned has been promoted by the trustees of the late Mr. PETER BROUGH, who left the handsome fortune of 153,926*l.* for the good of Paisley. He gave instructions in his will that 300*l.* a year should be expended in establishing and maintaining a science lectureship, and this sum his trustees laid apart, adding to it yearly whatever was over of this income, after meeting the demands made upon them by the will itself and various educational, charitable and religious objects. In this way they have amassed 11,000*l.*, and a year or two ago the Messrs. J. & P. COATS handed over to them extensive dyeworks in George Street, the ground on which these are built, and 3,000*l.* Quite recently they also received 3,000*l.* from the directors of the present School of Design, so that now they are in possession of about 17,000*l.*, a free site, and buildings which, with slight alterations, can easily be adapted for the practical side of the teaching given in such institutions. Accordingly, they have called into existence a board of governors, to whom they have entrusted their funds and properties, and also the building and management of the new school. They are all members of the new Board, but in addition to them there are gentlemen who worthily represent the culture and industries of the town. Steps have been taken for reporting on the possibilities of the site granted by Messrs. COATS, and there will be no delay in forwarding the erection of this school, which will prove a great boon to the inhabitants of the thriving industrial town on the banks of the Cart.

THE decision given by Mr. LANE, Q.C., at the North London Police Court on Monday, is important because it recognises a difference between a mews and a street. There is no legal definition we believe of a mews in the

Building Acts. There is a clause, however, which refers to domestic buildings and stable buildings abutting on the rear upon mews, from which it might be inferred that the open space, rather than the combined space and stable buildings, is the mews. At any rate, although horses and carriages may pass along what is known as a mews in London it is hardly a public road or street. The County Council maintain the contrary and have tried to gain a decision in their favour. In an estate off the Green Lanes near Finsbury Park two streets were laid out to form two sides of a triangle, that is if prolonged, for there was no apex. The intervening space was to be utilised for mews. When application was made for authority to erect stables it was refused unless a road 40 feet wide could be made throughout, the effect of which would be that all the contemplated houses could not be erected, for there was no opening of that width allowed for. The builder continued his operations and was summoned. Mr. LANE in giving his decision said the space might for sanitary purposes be regarded as a street, but otherwise he considered it was no more a street than the place within a gentleman's gates which is used by tradesmen. The occupant of one of the stables would have no claim on any more of the enclosure than would be required for his horse or carriage to stand in. The summons was therefore dismissed.

THE Arthurian legends have gained fresh interest in our time, and if we need a symbolic representation of the trials of humanity in seeking after perfection, they will serve as well as the productions of the present race of poets in the Quartier Latin. It is questionable, however, whether too much has not been made of those which more immediately relate to the British King. The search after the Grail was a theme which demanded higher qualities in a narrator, and it is a pity it should be overshadowed by the domestic woes of a man who was incompetent to rule his wife. We are glad to find that the authorities of the public library of Boston, in their commission for paintings to Mr. E. A. ABBEY, have selected the older and more exalted series of subjects. Five of the pictures which are to illustrate *The Quest of the Holy Grail* are now to be seen in the Conduit Street Galleries. In spite of the defective lighting, it is evident that they are better than any work which Mr. ABBEY has hitherto produced in England. He has endeavoured to suggest genuine wall-painting on the canvas, and very successfully. The legend embodied was evidently the creation of ecclesiastics, and Sir GALAHAD is represented as a true son of the Church. A nun receives him as a baby from angel hands, and if he does not become a cleric it is not from the want of spiritual guides. We see him watching in the church before he receives his knighthood, and we see him with other knights receiving an episcopal blessing. But slight as was his contact with the secular world, GALAHAD was somehow affected by it, and accordingly he has not the grace which is necessary to rescue the Fisher King from his trance. The pictures are mystic and wonderful. It would be cruel to apply archæological tests to the architecture or the costumes. The selection of such a subject by Americans is remarkable, but probably it will be said that compensation is to be found in the Egyptian and Assyrian scenes which Mr. SARGENT painted and which puzzled visitors to the Royal Academy. Who knows whether we may not also see in time Greek and Buddhist legends depicted for the same building? Meanwhile we advise our readers to see Mr. ABBEY's pictures while the opportunity is afforded to them.

THE jury who will decide upon the most suitable plan for the projected Ghizeh Museum is definitely composed of the following members:—The Minister of Public Works as president, the members of the Egyptological Committee, the six Commissioners of the Public Debt; M. DAUMET, president of the Society of Architects in France; Mr. SOMERS CLARKE, architect; FRANZ PASHA, ex-architect-in-chief to the Wakfs Administration; and MANESCALCO BEY, architect-in-chief to the Egyptian Government. The four last-named will form the technical sub-committee to study and report upon the various plans. The competing plans are to be sent in not later than March 1.

SCOTTISH PORTRAITS AND LANDSCAPES.

THE exhibition which is now open at the Grafton Gallery will probably be considered to have more technical than general interest. It consists of a great many portraits by various painters, with some landscapes by the Rev. JOHN THOMSON. Few of the portraits represent people whose names are familiar to the average visitor to exhibitions. The landscapes are by a man who is rarely mentioned in books or articles about painting. But for students of art and archæology there is no doubt much to be found in the gallery which is worth attention, and moreover, as the pictures belong to private collections, the majority of them are as little known in Scotland as in England.

There are, for instance, fourteen works ascribed to GEORGE JAMESONE, the "Scottish VANDYKE," who flourished in the first half of the seventeenth century. In our opinion the most interesting among them is the *Earl of Moray*. This is a full length life-size figure and valuable as evidence of costume. The modern kilt was the invention of one of General WADE's army tailors, and did not form part of the garb of Old Gaul. The Earl of MORAY has the substitute which was long in use. A large scarf resembling a "maud" is twisted around him and is trussed up under a belt. The check is of such quiet colours it would not be accepted by English tourists as tartan. The works of ALLAN RAMSAY, who lived in the eighteenth century, are also deserving of notice. He was a favourite with Scottish gentlewomen, and he represented them and their costumes with a good deal of ability. He was fond of making them appear as rigid, but that was we suppose a sign of dignity and breeding. There are portraits by WILLIAM AIKMAN, GAVIN HAMILTON (one of whose paintings, No. 75, contains as odd a horse as ever appeared on canvas), DAVID MARTIN, W. ROBERTSON, St. CLAIR of Roslin, HERCULES SANDERS, D. SCOUGALL, &c.

Among the portraits those by RÆBURN are the most numerous (there are over eighty), and in execution they are the best. The occasional examples by him seen in the Winter Exhibitions of the Academy have been a surprise to many, for it seems strange that such a master should be so little known in England. RÆBURN is likely to be considered as ranking after REYNOLDS and GAINSBOROUGH; his countrymen will award him a higher position. Nature endowed him with the gifts that were requisite for a portraitist—an insight into character, a vigour of hand that could catch sudden expressions, sympathy with young and old, and the sound sense that would never allow a subject to be made ridiculous for the sake of a whim. Like so many of the Renaissance artists, he was for a time a goldsmith's apprentice, but out of love for painting he purchased his indentures. At first he practised in miniature, which seemed to be ill-adapted for a hand with RÆBURN's power. The works of REYNOLDS, which he was fortunate to behold, fascinated him, and he went off to Leicester Square as if an oracle was to be found there. The President was not jealous about a man between whose style and his own there was so much affinity. He allowed RÆBURN to work in his studio, advised him, and offered him money towards paying the cost of a residence in Rome. As the Scottish artist was not poor at the time he did not need any aid of the kind. RÆBURN lived for a couple of years in Italy. In 1787 he returned to Edinburgh to practise as a portraitist. He was then in his thirty-first year. The rest of his life was spent in Scotland. He died in 1823.

The esteem which REYNOLDS's works wrought in RÆBURN was abiding. The portraits in the Grafton Gallery suggest his indebtedness to the English artist. It must be observed, however, that RÆBURN was not a man who was ambitious to have his portraits taken for REYNOLDS's. He worked in as ample a manner, and we imagine that RÆBURN commonly employed much larger pencils than his idol. The handling is so bold one seems to be able to count the strokes. RÆBURN also avoided loading his colour. There are some portraits that seem to consist of the thinnest paints, and there is a general freedom from retouching. The *Mr. Wardrop* is a notable example. At the present time RÆBURN seems to be a better guide for students than REYNOLDS, at least on account of technique.

The subjects in the collection are varied, young and

old, men, women and children. We can only mention a few. In full-length figures RÆBURN was never stiff or stagey. *Sir Allan Macnab*, who was too old to appear with bare legs and with an absurd bonnet of undertaker's plumes, almost appeals for pity. *Captain Robert Hay* is depicted as a volunteer, and leans on his firelock without appearing as to the manner born. *Dr. Spens* is in action as an archer, and, although the Order of Foresters has made that sort of assumption ridiculous, RÆBURN's work is dignified. On the opposite wall is an earlier portrait of another archer by DAVID MARTIN, which sustains comparison with it. In all portraits which are supposed to be taken in the open air, RÆBURN is admirable in his backgrounds. They are not obtrusive, and yet they show no disrespect to nature. The *Mrs. Kinnear* appears seated leaning against a wall, and the grey of the masonry becomes a foil for the dress and face. In his indoor scenes he had no fear of red curtains or green curtains, but he avoids the stereotyped arrangement of them which was common at the time, and he is fond of repeating the colour on a chair. In the portrait of *Mrs. Stewart* there is a landscape as well as a red chair and a curtain, and all are well combined. *John Home*, the clergyman whose "My Name is Norval" has given him fame, although the tragedy no longer holds the stage, is shown in a green coat and is seated in a red chair. Some old gentlewomen wear soft Cashmere shawls of a creamy or yellow colour. *Colonel Lyon* is in a blue and white uniform sketching a scene, *Adam Rolland* is shown in a comfortable office with green curtains and chair, *John Tait* is represented showing his watch to his grandchild who plays with the seals, and the action appears as if it were accidental. The variety of colours which is found in the accessories of the portraits adds much to the interest of the whole if considered as works of art. The only cases which can be considered as partial failures are two examples of what are known as "fancy portraits." One is a dreamy youth, *William Ferguson*, which is unlike RÆBURN's works in style, and the other is a semi-nude boy in an awkward attitude.

Sir JOHN WATSON GORDON may be considered as the successor of RÆBURN. His portrait, *Professor John Wilson*, was taken at a time when "CHRISTOPHER NORTH" was crusty, but it expressed the power and beauty of a head that was worthy to be adopted as a model of JOVE himself. *James Hogg, the Ettrick Shepherd*, who was so often the pantaloons for WILSON's clowning, is characteristic of the shepherd and drover rather than of the laureate of fairydom. Near it are two remarkable representations of northern shrewdness, *Roderick Gray, Provost of Peterhead*, and *H. Houldsworth*. The portrait by S. GRAHAM-GILBERT of *James Hamilton*, once police commissioner of Glasgow, is as remarkable an example of characterisation as can be found in the Gallery. This Scottish FOUCHÉ might be playing a part in which vanity, cunning, persistency and mock modesty were needed. He is an unfathomable being, and yet one must feel that if he could be seen through the revelation would show only what was worthless. G. PAUL CHAMBERS was a prolific portrait painter, but unless he were in the right mood and satisfied with his sitter the result would not be gratifying. Two examples by him are in the Gallery. *Rachael* is not much better than a coloured photograph, but the *Rev. Dr. Anderson* is a capital work. CHAMBERS at his worst was, however, superior to WILLIAM DYCE, R.A., whose attempts are more to be deplored than those of the majority of incapable artists, for his method was a legacy to the Science and Art Department which is still working harm. HERDMAN's drawing of *Thomas Carlyle* in 1870 is one of the most vivid portraits of Mr. FROUDE's victim that has appeared. Sir D. MACNEE is represented by a portrait of *Mackay as Bailie Nicol Farvie*, which is so much superior to that painter's work we are almost disposed to doubt its authenticity.

Seventy years ago the Rev. JOHN THOMSON, who was parish minister of Duddingstone, near Edinburgh, was considered to be the most Scottish of the northern landscapists. Modern fiction has discovered interesting characters in the manses, but none of them surpasses THOMSON. He belonged to a clerical family, and his delight in painting and music was only a phase of his religious character, an expression of worship in another form, for he exemplified Mr. RUSKIN's maxim that all great

art is praise. He was reverential towards nature, especially as it was seen in the northern regions of Scotland, and he considered he was happy to be the means of recording its grandeur. THOMSON was persuaded to exhibit in Edinburgh, but he could not be induced to send any of his works to England. He was not solicitous of fame, and he felt that his neighbours and countrymen would alone be able to appreciate his aim when he combined painting with his ministerial office, as if the two were closely related. His aspirations were not unlike those of many of the old monks, but it would be ruin to him if he proposed to paint the walls of his church with Scripture scenes. THOMSON'S landscapes were not judged by rules that were applied to contemporary works. The exceptional favour which he enjoyed was owing to the belief that, like "Old Mortality," it was his mission to perpetuate things of which Scotsmen were proud. The references to his pictures in an imaginary conversation between CHRISTOPHER NORTH and JAMES HOGG (*Noctes Ambrosianæ*, No. xlviii.) is an instance:—

NORTH: Mr. Thomson, of Duddingstone, is now our greatest landscape painter. In what sullen skies he sometimes shrouds the solitary moors!

SHEPHERD: And wi' what blinks o' beauty he aften brings out frae beneath the clouds the spire o' some pastoral parish kirk, till you feel it is the Sabbath!

NORTH: Time and decay crumbling his castles seem to be warring against the very living rock—and we feel their endurance in their desolation.

SHEPHERD: I never look at his roarin' rivers wi' a' their precipices without thinking, some hoo or ither, o' Sir William Wallace! They seem to belong to an unconquerable country.

NORTH: Yes, James, he is a patriotic painter. Moor, mountain and glen—castle, hall and hut—all breathe sternly or sweetly o' auld Scotland. So do his seas and his firths—roll, roar, blacken and whiten with Caledonia—from the Mull of Galloway to Cape Wrath. Or when summer stillness is upon them, are not all the soft, shadowy, pastoral hills Scottish, that in their still deep transparency invert their summits in the transfiguring magic of the far sleeping main?

His pictures are now seen in the Grafton Gallery under conditions that he could not have anticipated, and will be judged by canons which were unknown to him. THOMSON felt he could not be too faithful to nature, and he endeavoured to represent not only form but the colours which sometimes seem to vary from moment to moment in the North. The view of *Loch Scavaig, Skye*, is one remarkable instance, for although the colours on the rocks now appear rather confused, it will be evident to every painter they once expressed much of the witchery of light and shade. Where as in that view, or in *Loch Cormirk, Skye*, and in many of the coast scenes THOMSON was satisfied with reality, he is always admirable. But where he fails is when he wishes to show his respect for a scene by endeavouring to elevate it in order to make it correspond with the examples of the ancient masters. He could have had few opportunities to study their works and probably was compelled to rely on engravings. It is in some of his foregrounds THOMSON reveals these influences upon him. He will draw a scene like *Castle Urquhart* with fidelity, but the effect of distance will be suggested by conventionalities that are out of keeping. To give effect he also introduces trees which would puzzle a northern forester, as in the pictures called *Dunure Castle* and *Innerwick Castle*. His *Stirling Castle* at first seems to be an Italian view, but after study one perceives that the greater part of it is true to nature. With his cliffs and rocky scenes we suppose THOMSON felt that conventions were out of place, as well as in his sombre *Martyrs' Tombs on the Moss of Lockinkett, Galloway*.

Fortunately the majority of the paintings do not appear to have any claims to relationship with the "great masters," the work of men who scorned to accept nature as it appeared. The castled crags are a revelation of the shrewdness with which geological catalogues were turned to account in Scotland. The view of *St. Abbs Head* recalls the report of CROMWELL, who said it was a place "where ten men to hinder are better than forty to make their way." The castles were sufficiently impregnable to allow less than ten men to withstand forty. *Innerwick Castle* does not suggest a great fortress, but a handful of faithful retainers in it withstood a siege. We are told "they were honoured with an assault with large cannon, while hagbutters were placed so as to prevent the defenders from appearing at the windows." *Tantallon Castle* is the subject of two of THOMSON'S paint-

ings. As it was a stronghold of the DOUGLASSES, it was supposed to be unapproachable, and the utmost absurdity was suggested by the old proverb—

Ding down Tantallon—
Make a brig to the Bass.

From the land side it appears of little account, but seen from the sea it is among the most majestic of ruins, and, as THOMSON suggests, is not unworthy of the promontory on which it was erected, or of the fine coast of which it appears to form the defence. THOMSON also made a couple of paintings of *Fast Castle*, and although the colours have suffered the views bear out SCOTT'S words when he said, "Fast Castle is more like the nest of some gigantic roc or condor than a dwelling for human creatures." It is sometimes supposed that *Fast Castle* was the residence of RAVENSWOOD, and the scene of many of the incidents in the "Bride of Lammermoor." SCOTT, in his sly way, neither admits nor denies the truth of the statement, saying, "The author is not competent to judge of the resemblance betwixt the real and imaginary scene, having never seen *Fast Castle* except from the sea. But fortalices of this description are found occupying, like ospreys' nests, projecting rocks or promontories in many parts of the eastern coast of Scotland, and the position of *Fast Castle* seems certainly to resemble that of *Wolf's Crag* as much as any other, while its vicinity to the mountain ridge of *Lammermoor* renders the assimilation a probable one."

We must not linger over the associations which are excited by the representations of Conway, Ravensheugh, Kilbaun, Eclandonan, &c., when seen in a strange land. For architects they have more attraction than for ordinary visitors, for most of those lofty and inhospitable residences are in keeping with their sites, and justify the lines which JAMES ALVES wrote in the last century:—

Our barren rocks which English wits detest,
And make the butt of many a clumsy jest,
By Art transformed they shape the full sublime,
And strength and grandeur to convenience join;
Defy for ages Time's corroding rust,
When mould'ring bricks are mingled with the dust.

THOMSON is never more successful than when he suggests the relationship between the fortalice and the cliff. When, as in *Conway Castle*, he depicts the building alone he becomes prosy.

From the castles to the cases in the Gallery is only a rational transition. They display weapons of defence, plate, trophies and historical curiosities. There are examples of several varieties of the old Scottish broadsword, which are as picturesque as effective, skians and targets, the last showing generally an arrangement of the studs which was derived from old Celtic forms. The jewellery is, on the whole, inferior to what is made in Birmingham and sold to tourists as native work, but the silver plate, with the exception of the cups for church use, is fine in form and in ornament. There is one silver tankard with repoussé work which will probably excite more longing than any picture on the walls. In these days of revivals the "tirling-pin" seen in one of the cases might be worth utilising. It was a substitute for a door-knocker. It consisted of a notched bar over which a ring was quickly passed to serve as a summons when a door was about to be opened. A specimen of another piece of ironwork which we hope will always be obsolete—the thumbscrews—can also be observed, with many other things which were necessary for use in peace and war in Scotland.

THE END OF THE RENAISSANCE.—II.*

THE knowledge which enabled a multitude of Italians to paint, carve and design with facility had also its counterpart in architecture during the sixteenth century. The former kind was circulated, as it were, by the direct agency of man, just as the scholastic knowledge in the Mediaeval universities or the principles of the common law in England. The Renaissance treatises on painting and sculpture are not precise. DA VINCI'S, which is the best,

* *Histoire de l'Art pendant la Renaissance*. Par Eugène Müntz, Membre de l'Institut, Conservateur des Collections de l'Ecole Nationale des Beaux-Arts. III. Italie: La Fin de la Renaissance. Paris: Hachette et Cie.

was probably found to be as difficult for utilisation by his contemporaries as it is in our time. With all the facilities which we possess for exemplifying the various stages of a picture or a piece of sculpture, it may be doubted whether a treatise that can be called practical on painting or sculpture is feasible. A master will find that his lessons are only appreciated when exemplified with the aid of a pencil or a tool. The forms are too varied, the lines too subtle, to be defined in a printed page. With architecture, on the contrary, in which right lines and unvarying geometric figures are elements, the written or printed treatise can almost supersede oral discourses. The laws of the art appeal to the intellect as well as to the eye, and are not to be understood without a concentration of attention for a longer or a shorter time, according to the capacity of the student.

In the sixteenth century men were able to hear about new buildings equally with new pictures or new statues, but the architects did not depend on the knowledge communicated by itinerant critics. Treatises on the art were at their disposal. The period we are considering was differentiated from those preceding it by the publication of the books of SERLIO, VIGNOLA and PALLADIO, which went beyond ALBERTI'S "De Re Ædificatoria" in conveying information that could be turned to account without much labour. The effect of the books was to create a standard of art, for in the sixteenth century every author was esteemed, and to put a check on license. Architects had also in Rome antique buildings which received as much reverence as if they came from superhuman hands. Thanks to antiquity and the printing press, the art of architecture was more free from extravagance in the sixteenth century than the other arts. M. EUGENE MÜNTZ is therefore able to commence the part devoted to architecture in his volume by saying, "It is impossible to deny that it was in the region of architecture the grandest works were accomplished in the end of the Renaissance. While sculpture and painting became more and more frivolous, architecture became more learned and serious." The sobriety of style is the more remarkable when we consider the temptations of the time and the absence of uniformity and training among the architects. On the latter subject M. MÜNTZ writes:

It will not be uninteresting to consider the origin of the great architects belonging to the last period of the Renaissance. Peruzzi, Giulio Romano, Serlio, Vignola, Vasari, Buontalenti, P. Tibaldi commenced as painters; Michel Angelo, Sansovino, Ammanati, as sculptors; Antonio San Gallo, San Micheli, Alessi and Palladio were devoted to the art of building from their youth. As happened at an earlier time, some of the architects were likewise contractors. For example, Battista da San Gallo and Giovanni Mangone were employed by the Papal Court as examiners of the work of other men, and contractors on their own account. Vasari, on the other hand, delegated the duty of directing the construction of the buildings he designed to subalterns, to a certain Master Bernard in particular. The architect was considered as legally responsible for failures. After the fall of the vaulting of the Library of St. Mark, Sansovino was imprisoned and fined 1,000 golden marks. It was with much difficulty he was able to explain his innocence, and to obtain the repayment of the sums which were wrung from him.

For the first time in the Renaissance architecture was not considered merely as an affair of single buildings. Attempts were made to improve the streets in which they stood. In Genoa it appears the people of a district united in order to insure that the axis of the Strada Nuova should be laid out in such a way as to afford pleasing views, an example that could be followed with advantage in our time. In regarding buildings as if they were only units and of diminished value unless in combination, more modesty of character for single buildings would be insured. The employment of wooden models instead of drawings was a means to the same end. The author of "Henry IV. Part II." recommends the use of models in order to save building owners from going beyond their means, but they were no less useful in putting a check on redundancy of ornamentation. They were included among the works which an architect could take up without loss of caste. In Florence M. MÜNTZ tells us not only JEAN BOLOGNE, BUONTALENTI and DOSIO were occupied with them, but one of the Medicean princes did not disdain to fashion a model. LABACCO was paid 5,184 golden crowns (over 7,000*l.*) for one representing SAN GALLO'S design for St. Peter's; MICHEL ANGELO'S was suggested by one of clay costing only

25 crowns, and it gained the commission. The employment of marbles was also conducive to sobriety of treatment.

The architects of the time would not be men if they did not commit errors. MICHEL ANGELO, who might be supposed to care only for fine sweeping lines, introduced the broken pediments, which the Dutchmen ought to have acknowledged by a statue at least. There were many other puerilities to be debited to him, and they justify M. CHARLES GARNIER in saying the Florentine was not familiar with the grammar of the art, and Mr. FERGUSSON when he calls attention to "those unconstructive absurdities which disfigure all the buildings of that great man." M. EUGENE MÜNTZ is more temperate in his criticism. He does not deny that MICHEL ANGELO was indifferent to repose, that the right line was odious to him and was eventually broken, and that the calmness and purity of the old style of Florentine façades were disturbed by his pilasters, niches and festoons; but he maintains that the artist's errors were often advantageous, as they were the means of introducing new ideas, besides leading to the creation of works of the value of the chapel of the MEDICIS and the dome of St. Peter's. It is unquestionable that much modern work is more allied to MICHEL ANGELO'S attempts than to the work of any of the other Renaissance architects. The efforts to avoid monotony, even at the cost of sacrificing qualities which impart repose to a building, may claim to have had his inspiration. It was only natural that a man who had devoted so much of his life to the study of the human form, and who was cognisant of the extraordinary variety of contours which are to be found in all parts of the body, should be incapable to realise that the tradition of architecture was in favour of masses expressive of their inertia as approaching the nearest to the ideal of art.

M. MÜNTZ, with all his admiration for MICHEL ANGELO, places PERUZZI above him as an architect. But the modesty or timidity of the man was an obstacle to his attainment of the practice he merited. In the sixteenth as in the nineteenth century it was requisite for an architect to be mindful of his own interests. VASARI, who was acquainted with all the conditions of practice, warns his readers against an imitation of PERUZZI'S conduct. He was employed by popes, cardinals and princes without much advantage to himself, for, says VASARI, "constant dunning is sometimes a virtue, to be lenient with some clients is an error." When he was dying his patrons felt remorse and promises were made to him, but it was too late. According to VASARI there never was an equal to PERUZZI in architecture, and his Farnesina "should rather be described as a thing born than as one merely built." The Massimi Palace was designed by him, but he directed no more than the lower part of the works. We can see that he thought of a building as a whole, and, however attentive to details, he never allowed them to interfere with the general effect. M. MÜNTZ calls him "le dernier harmoniste à la façon de BRAMANTE," and the phrase epitomises PERUZZI'S character as an architect.

Another famous artist of the century was ANDREA PALLADIO, the last of a grand race. He has given a name to a style, and indeed to many all Renaissance Italian is only Palladian under various shapes. Yet PALLADIO was not the name of the architect's family, and it is no longer possible to say what his surname should have been. He was only a poor stonecutter, the son of a miller, and it has yet to be discovered when he was born and in what quarter of Vicenza. Concerning his works M. MÜNTZ writes:—

The churches constructed by Palladio, in Venice (San Giorgio Maggiore commenced in 1560, the façade of San Francesco alla Vigna, 1568, il Redentore, 1570), were a veritable revolution. In doubling or tripling the proportions of certain factors, in making columns or pilasters of the same height as the entire façade (as had been done by Alberti in the church of St. Andrew, Mantua), he united simplicity to grandeur. His ideal was to conciliate the forms of antique temples with the requirements of Christian worship. Not less original is the cloister of Santa Giustina, at Padua. All is united rigorously; the influence of a firm will is seen in the least details. It is, however, in his native city, Vicenza, that the great artist has left his masterpieces. The construction of the Basilica, the Olympic Theatre, the "loggia del Delegato," the Rotunda, besides innumerable palaces and country villas, make it one of the most attractive in Italy. In the Basilica, where he had to consolidate the exterior of an old Gothic edifice, and to give it a façade in harmony with the taste of the Renaissance, he realised a double "tour de force" in accommodation and in decora-

tion. He demonstrated that in order to innovate it suffices to combine in a different manner engaged columns, coupled columns, arches, balustrades, statues and the other elements employed during a century and a half. In that way he succeeded in attaining an extreme variety and a great boldness of combinations; lines that were pure and yet animated; forms that were ample without being heavy. The Olympic Theatre is a mirage—Paul Veronese in architecture, through its profusion of statues on the columns and in the niches, its bas-reliefs and astonishing perspectives, its grandiose portals as in the modern boulevards, the general lines being, however, noble and calm.

From what we have said the character of the concluding volume of the history of the Italian Renaissance can be inferred. M. EUGENE MÜNTZ makes it clear that styles are connected with the idiosyncrasies of artists, and therefore a history of art must have a biographical basis. All the fine arts are treated in an uniform manner, and the abundance of beautiful and most exact illustrations will be found to be fitting auxiliaries to the descriptions. His success in dealing with the Italian division is a guarantee that the forthcoming volumes on the Renaissance in France, Germany and England will be no less satisfactory.

MANCHESTER ACADEMY OF FINE ARTS.

THE annual meeting of members of the Manchester Academy was held on Monday. The report stated that an experiment was tried last year to establish a plan of including as part of the business of the annual meeting the election to full membership from the body of the associates, believing that by such a change they might more certainly rely upon having a goodly muster. However, the Council upon this occasion reverted to the original custom, and the work of the ladies and gentlemen whose names were to be submitted for consideration might be fairly seen and discussed during the present week in the exhibition. A general meeting would be held next Monday to receive and examine voting papers, when the result of the investigations would be declared and the names of the successful candidates duly published. Respecting the last spring exhibition, the Council were pleased to be able to report that it was an entire success. Forty-five works found purchasers at a net price of 724*l.* 1*s.*, as compared with 457*l.* for thirty-four works sold in the spring exhibition of 1893. With regard to the work of the life classes during the session 1893-94, studies were submitted from eighteen ladies, whilst but two gentlemen students sent in work for inspection. The specimens as a whole were not of a highly satisfactory character, being considered as rather too slight and not displaying that spirit of earnestness necessary to the achievement of great things in art and study. The only awards granted were as follows:—To Miss Lucy Bowker and Miss Amy Howarth a free studentship for the sessions 1894-95 and 1895-96, and to Miss Mary Davis for the session 1894-95. Regret was expressed that at the exhibition last October many of the Society's leading and popular members failed to send in contributions. The Council believed that had more loyalty been displayed they would have now been able to record a much more satisfactory result. The Academy life classes for the present session opened on October 1, 1894, with four gentlemen and twenty-eight lady students, most of whom were re-elected from last session. Since the opening date the ladies' life class had been considerably augmented, the total number of students being now forty-four. In conclusion reference was made to the loss which the Academy had sustained by the death of Mr. J. Murgatroyd and Mr. W. P. Norris, two gentlemen who had always taken a keen interest in art matters. Two resignations were recorded, Mr. Basil Bradley and Mr. E. Salomons. The register showed at present forty-two members, thirty-six associates, forty-four students and eleven honorary members and sixty-eight annual subscribers. The statement of accounts presented by the honorary treasurer showed a balance of 135*l.* The officers were re-elected as follows:—President, Mr. H. C. Whaite; vice-president, Mr. R. Barber; treasurer, Mr. W. Artingstall; hon. secretary, Mr. Elias Bancroft; hon. literary secretary, Mr. W. Herbert Johnston. The Council was composed as under:—Mr. J. Houghton Hague, Mr. John Cassidy, Miss M. F. Monkhouse, Miss E. Magnus and Mr. J. H. Davis Colley.

LORD HOUGHTON ON ART IN IRELAND.

THE prizes won by the students of the Dublin School of Art were distributed by the Lord Lieutenant. His Excellency said:—The report which I hold in my hand, particularly read in the light of the interesting speeches of Dr. Ball, the director of the Science and Art Museum, and Mr. Brennan, is one, I think, of which the teachers and the students may well be proud. I see it stated in the report that prizes in the national awards are yearly becoming more difficult to win owing to increased competition, and that, therefore,

they do not consider that the school has done otherwise than well. Well, that is a very fair statement to make in the interests of the school, and although the fact may press sometimes hardly on individuals, it is one that we cannot speak of with regret, because it shows that the general standard all over the country is a higher one than it was before. And before proceeding to speak on what I may call the more picturesque part of the work of the school I would like for one moment to refer to the classes for science and geometry, which, I see, have sustained a sad loss, for although these subjects are not so generally attractive, for that very reason I think attention ought to be drawn to the useful part that is played by instruction of that kind in the education of the country. As regards the more purely artistic side of art study, I think that we must all agree that the school is to be congratulated on the general measure of success it has obtained. And I most heartily agree with what fell from Dr. Ball, that the object of this school is not to produce one or two brilliant geniuses, although I am not by any means sure that it does not do so now and then, but that the object is to sustain a high level of general work which will enable the students to lead useful lives in any branch of artistic study that they may afterwards undertake. And I think that there is no more gratifying feature in the whole report than that to which attention has been already drawn, namely, that of the association of this School of Art with the improvement of the products of Irish industry, such as lace, and also in other branches. I notice with very great pleasure the successes which have been gained under the wing of the Royal Dublin Society and with the Irish Industries Association at that very successful local exhibition which was held in Kirkby Lonsdale, in Westmorland, and in which I may say I take a personal interest. If, as I believe is likely to be the case, an Art and Crafts Exhibition is held in Dublin, that will, I trust, give a still further impetus in that direction, because I think, whatever our views on the art of the present day may be, we must all agree that there is a great deal to be done in the direction of improving the form of many articles of common use. This we know is an age of wholesale production, and I think that the life of a school of this kind ought to be one of perpetual struggling against mechanical reproduction. The reproduction, the endless reproduction, of even good designs is bad enough, but when it comes to the reproduction of unmeaning or even actually bad designs by hundreds and thousands, that is a thing against which schools of this kind ought to maintain a perpetual struggle. What is desirable is to restore to articles of everyday use some stamp of the individuality of our artists, which is what makes so precious to us the work of artists of the old days, even when humble materials were used for objects of everyday use. It is only by such means as these that the general standard of taste is to be raised. That it is being raised I think may fairly be deduced from what Dr. Ball told us of the use that is made of the museum of which he is also director. His figures appear to me to be exceedingly striking. And even, as he humorously pointed out, if some deduction is to be made for the presence of tourists, I do not know that we have any reason to complain. A certain depreciation, as we all know, attaches to the word "tourist;" I am not quite sure why, for tourists are human beings, and we have many of us been tourists ourselves. And if they had come, a certain number, on cars or otherwise, to view the museums, I do not know why anybody should complain. But I think it is very evident from what Dr. Ball said that the casual visitors form but a very small part of those who visit that most interesting collection. And before leaving this branch of the subject I may say with what pleasure I heard the figures that he gave describing the use which is made of that museum on Sunday. I am one of those who believe that the admission of persons interested in art to the great collections on Sunday, under proper restrictions, is a distinct assistance instead of being a bar to proper and reverent use of the day. Well, I said that the object of this school is to raise the general standard of taste. And it has sometimes occurred to me, as it may to you, to ask, what is "taste?" There is no known code that may be laid down at any given moment to say what taste is. The taste of one age is not the taste of another. I think that it can only be described as the best opinion on matters of art of the best minds of the age in which we live. No doubt there are some points on which most ages have been agreed. Most ages have been agreed, for instance, that the Parthenon, Salisbury Cathedral, and the Campanile in Florence are fine buildings. But in other matters which seem to us as easy of decision as these, the divergence of taste, as we know, has been exceedingly wide. To some it is disheartening that at certain periods of history the artistic sense seems to have died down altogether. There was a period in the present century when a sort of wave of ugliness seemed to pass over the country, of ugliness in architecture, ugliness in furniture and ugliness in dress, the delivery from which will be always inseparably associated with the name of Mr. Ruskin. There have been periods, I say, of what we consider bad taste, and perhaps there may be again,

but I think that the duty of the student is a simple one enough. The duty of the student is to look to the best minds, as I have said, of his own day, but he is never to forget at the same time that he has a mind of his own. The ideal student to my mind should exhibit a proper mixture of the two opposing but not incompatible qualities of reverence and independence. Unless he has reverence both for the great minds of the past and the great minds of the day more approaching to his own, he is never likely to become an artist in any branch. But, if he carries his reverence to such an extent as to sacrifice his individual independence of mind, he will become and remain a mere slavish copyist. In this school you are all engaged in one form or another in the discovery of what is beautiful, and in learning to know in what way to turn that knowledge to account. As for the spirit in which that search is best made, I think I may well express what I mean by quoting the words of a fine critic and writer who has lately been taken from us. He says:—"The more we reflect, the more we are led to the conviction that art cannot neglect correspondence between beauty and truth, beauty and goodness, and beauty and use." And I would particularly draw your attention to the word "use." In proportion as beauty includes these elements, it is vigorous, enduring, vital and universal for all time and for all nations. I thank you very heartily for your kindness in passing this vote of thanks.

THE LATE SIR CHARLES NEWTON.

ON Wednesday a meeting of the Hellenic Society was held when Professor Jebb, M.P., the president, spoke upon the services of the late Sir Charles Newton.

Professor Jebb said that at the first general meeting of the Society which had been held since the death of Sir Charles Newton, it was fitting that some tribute should be rendered to the memory of one whom the Hellenic Society might justly regard as chief among its founders; whose presence and influence did more than anything else to carry it successfully through the earliest days of its existence, and who, to the end of his life, took the keenest interest in its growing prosperity. Newton's life divided itself into three well-marked chapters. The first contained the thirty-six years from his birth in 1816 to 1852; it was the period of preparative studies. The second began in 1852 with his consulship at Mitylene, and closed in 1861 with his return to London as the head of his department at the British Museum; it comprised the period of travel and discovery in the Levant. In the third chapter, from 1861 onwards, he was the organiser and administrator; the recognised head of classical archaeology in this country; the active supporter of all enterprises, whether originating at home or abroad, which could extend the knowledge of antiquity, or which promised to advance an object always so near to his heart, the addition of new treasures to our great national collection. After sketching the chief events of Sir Charles Newton's life, the works he wrote and his achievements in exploration, Professor Jebb went on to deal with Sir Charles's connection with the Hellenic Society. He said:—"When the inaugural meeting of this Society was held in June, 1879, it was to him that the supporters of the project primarily turned for countenance and counsel. During the first six years of the Society's life he was constantly in the chair at our meetings; nor is it too much to say that his guidance and his name must be reckoned among the chief causes, not only of the early and rapid success which attended the Hellenic Society, but also of the position in which it is now established. In 1883 his aid and counsel were also valuable in helping to institute that British School at Athens which, in the face of difficulties not experienced by the similar schools of other nations, has done so much to uphold the reputation of our country in the field of archaeological research. This is merely a bare outline of Newton's life-work; but even so slight a sketch must not close without some attempt to indicate the leading characteristics of the man's mind and nature. First, as to his attitude towards his chosen studies. It has lately been said, by one well fitted to judge, that the ancient monuments interested Newton rather on the historical side than on the mythological or the artistic. Indeed his own words can be quoted, "I am first an historian, and secondly an archaeologist." This may seem a hard saying, but I believe that it is true, though it perhaps needs some elucidation. It means that Newton was never a specialist in the limited modern sense; it was classical antiquity as a whole that had a spell for him; it was in the intense desire to reconstruct and revivify this antiquity that he so closely and indefatigably scanned every monument of any kind that could tell him anything about it. His strongest feeling in early manhood was that ancient literature, in which he was well versed, told only part of the story. His address at Oxford in 1850—which now stands first in his volume of essays—begins with words which strike the keynote of his work, "The record of the human past is not all contained in printed books."

Hence the peculiar interest which he always took in epigraphy; here he felt that he came closest to ancient lives and minds; his two essays on Greek inscriptions, published in 1876 and 1878 (the fourth and fifth of the collected essays), illustrate this in full; few productions of his pen are more striking. Now, this desire to apprehend the life of antiquity is often associated with the kind of imagination which seeks vivid or rhetorical utterance in language; it was distinctive of Newton that, in his case, there was absolutely no such tendency; on the contrary, he recoiled from it. The life of his imagination was an inward life—so inward that he might often seem unimaginative; a life which he wished to share only with the careful, laborious, exact student, but did not choose to share with the outward world. Witness the guides which he prepared to his galleries at the British Museum—exemplifying his conception of a scientific catalogue as the outcome of a life devoted to a single study—but making no concession to a popular desire for more elementary knowledge. When, in 1880, he became the first Professor of Archaeology at University College, London, the stamp of his teaching showed the same bent. His sustained, though undemonstrative, ardour was singularly allied with caution. Without being cynical, he was wary in a degree which sometimes approached to cynicism; in discriminating between what was merely probable, and what might be accounted certain, he leaned to the sceptical side, and he was imbued with the sentiment which Aristotle attributes to old age, that "most things are unsatisfactory." No man was less sanguine, or quicker to foresee the difficulties of a project; but, once engaged in it, he was tenacious and intrepid. His self-contained manner was due in part to the natural fastidiousness of his taste; it was only when he felt secure, for the time, against jarring incidents—which, even when slight, affected him like physical pain—that he completely unbent, and showed the most genial side of his nature. In colleagues he looked for the highest standard of work; his demands on subordinates were strict; he was an exacting, but also a stimulating, ruler. If the essence of his character could be contained in a phrase, it might perhaps be described as severe enthusiasm. To those who knew him but slightly, the severity—not harshness, but the severity as of good Greek sculpture—might be more evident than the enthusiasm; but a nearer knowledge revealed the man in whom an inward fire had burned steadily from youth upwards—a sacred fire, little seen, not to be extinguished, and shaken neither by any wavering of purpose nor by the breath of any vulgar ambition. His many honours, academic or public, were prized by him in proportion as he took them to be recognitions, not merely of eminence generally, but of success in the precise aims which he had set before himself. The chief source of satisfaction to him in his later years was to think that classical archaeology had gained so much ground in England, and that he had helped it forward; but this feeling was deeply tinged with melancholy; he thought of himself as the leader through the wilderness, who was not to enter the promised land. There are minds, perhaps, in which lifelong conversation with the past so confirms the habit of retrospect that the difficulties of earlier years always loom large, even after subsequent successes; so at least it seemed to be with him. But to others it will appear that, however distant the point gained in his lifetime may have been from his ideal, still the cause to which he rendered such abundant service was already gained before he died. In the future of classical studies, so long as they may exist in this country, the place of archaeology, not as an accident but as an essential, is assured beyond the danger of overthrow. Newton has been recently compared, and not unjustly, with Winckelmann. The German worked in the dawn, the Englishman, though still in the morning hours, yet in a far clearer light; between them, however, there is this intrinsic resemblance, that in both the mainspring of a devotion which ended only with life was a native instinct, intensely strong and lucid, for the spirit and the charm of classical antiquity. There are those in this room to whom the impressive personality of the master whom we commemorate will be a lasting recollection—that singularly fine head and pose, which themselves seemed to announce some kinship with ancient Hellas—that voice which so often within these walls expressed the knowledge thrice refined by ripe study and experience; a few years more and these will be only traditions; but to our successors, the members of this Society in days to come, the history of learning in Europe will bear witness that no body formed for the promotion of Hellenic studies could have entered upon existence with a worthier sanction, or could desire better auspices for its future, than those which are afforded by the name of Charles Newton.

The Athens Correspondent of the *Standard* says that Professor Durm, the German architect summoned by the Greek Government to take in hand the necessary repairs to the Parthenon, has concluded his preliminary inspection. His opinion is that the restoration can be carried out without materially affecting the general character of the structure.

TESSERÆ.

The Temple of Zeus, Olympia.

OLYMPIA consists of two very distinct parts, namely, the precinct of Zeus, and the edifices lying without the same. The precinct of Zeus, known also as the Altis and the Sacred Grove, is a walled enclosure, forming an irregular quadrangle, with a mean length of 4,000 feet from east to west (parallel with the river), and a mean width of 2,000 feet from north to south (from the foot of the mountain to the river). Within this enclosure stood the altars, temples, sanctuaries, treasuries and other buildings for the use of the officials and for the reception of the city's guests attending the festival. The space not occupied by these structures was filled with statues and votive offerings, which, as time went on, were multiplied till at last only the roadways traversing Altis were free. Pausanias has left us a precise description of Altis (written A.D. 173), which is still extant. The precinct of Zeus may be considered as divided into two parts, a northern and a southern. In the southern portion the Temple of Zeus forms the central point, around which are grouped the lesser monuments. The temple was never entirely covered with *débris*, but not till now could its whole ground-plan be seen. It was a building in character like the Parthenon, but still more imposing, for it had only six columns on its narrower façades, making its architrave blocks so much more massive. There still remains in the vestibule of the temple the ancient mosaic pavement, composed of pebbles of different colours from the Alpheios, representing Tritons and Cupids. We can measure exactly the cella; we recognise distinctly the site where stood the Colossus erected by Phidias; we see the traces of the interior columns, the supports of the galleries, to which wooden stairways led up. The material of the temple was a friable shell limestone coated with white stucco of the finest quality. The moulding flute with lions' heads spouting water, as also the flags forming the roof of the temple, were of Parian marble. In Roman times the edifice underwent a thorough restoration, the material employed being Pentelic marble. This work of restoration can be distinguished both by the material and by the marks made by the workmen on the blocks of stone. Still, the edifice as a whole is a monumental example of a Doric temple, and it is of the highest value for the history of that style of architecture. It is the work of Libon, a native artist, and dates from a time only twenty years prior to the building of the Parthenon. We find here grander proportions, a more admirable earnestness, a purer Doric than in the more celebrated temple at Athens.

The Steel-yard and the Hanseatic Merchants.

In the Utrecht treaty of 1474 the place belonging to the Hanseatic merchants is called *Staelhof*, *alias* *Stylyard*—a name which is explained by Hudson Turner and by Peter Cunningham as signifying the spot where once the great public beam and balance stood, by which all goods were weighed on landing in order to secure the king's toll. The original Guildhall of the Cologne merchants in the thirteenth century, the *Aula Teutonicorum*, was situated close to the ancient city gate on the water side, the name of which is still preserved in the adjacent lane, Dowgate. In the following centuries several estates in the vicinity were added by purchase: the house of a knight, Sir Thomas of Salisbury; that of Sir Richard Lyons; another house, given originally by Richard II. to a follower of his queen, Ann of Bohemia; five houses on the western side of Windgose Lane, and several more. In the sixteenth century the whole property was united, and offered a considerable aspect, the old hall being a huge stone building with three round gates opening into Thames Street. Each of them was adorned with a Latin distich, the middle of one ascribed to Thomas More, and not unworthy of his genius:—*"Aurum blanditiæ pater est natusque doloris; Qui caret hoc moriet, qui tenet, hic metuit."* Two large pictures by Holbein, a description of which is still extant, covered part of the inner walls. Here the worthy merchants used to assemble and conduct their mercantile and social affairs; here they also dined together on certain great occasions. On the bank of the river there had risen a stately mansion, the residence of the Steel-yard master. The space between the two edifices served as a garden with fruit trees and vines, where the young people used to amuse themselves with various games, but were strictly forbidden by a fine of five shillings to pluck a plum or an apple. A house in front with the hall was the celebrated Rhenish winehouse, the very spot, probably, where since the days of Henry II., who first sanctioned the free importation of hock to the citizens of Cologne, this wine had been sold without intermission. Thomas Nash, in his *"Pierce Penilesse, his Supplication to the Devil,"* makes a sluggard say, "Let us go to the Stilliard and drink Rhenish wine." And in one of Webster's plays we read:—"I come to entreat you to meet him this afternoon at the Rhenish winehouse in the Stillyard. Will you steal forth and taste of a Dutch bun and a keg of

sturgeon?" The same place was famous for its smoked ox tongues, which explains the allusion made in Nobbes's *"Bride,"* "Who would let a cit (whose teeth are rotten out with sweetmeat his mother brings him from goshippings) breath upon her vernish for the promise of a dry neat's tongue and a pottle of Rhenish at the Stillyard," &c. Even after the great conflagration, Blount says, in his *"Glossography:"*—"The Steel-yard was lately famous for Rhenish wines, neat's tongues," &c. The same place is adorned by a large beerhouse, still bearing the name of the Steel-yard, and hanging out as its sign an immense gilt grape, such as the traveller meets with in almost every street of the old German cities. Various other halls, dwelling-houses of the merchants and their clerks, files of warehouses, and a wharf, with a large crane, filled the remaining space, a ground plan of which was taken the year after the fire by the indefatigable Hollar. The whole place had rather the look of a small city fortified by walls, which on certain occasions, when the foreign burghers could not avoid having a quarrel with their neighbours, who, perhaps, exasperated by their many privileges, fought them manfully, served as an excellent refuge for the weaker side. All this massive grandeur has been swept away by time and fire.

William Gandy.

Whatever may have been the exact period of the change in Reynolds's style, Northcote and Leslie agree that the hints which kindled his genius were derived from the works of William Gandy. This gifted man was an itinerant artist, who roved through Devonshire and Cornwall, and died about the time when Joshua was born. Lazy, gluttonous, improvident and irascible, he dashed off likenesses at a couple of guineas a piece, with no other care than to obtain with as little trouble as possible the money which would purchase him a luxurious meal. "His portraits," says Northcote, "are slight and sketchy, and show more of genius than of labour; they, indeed, demonstrate facility, feeling and nice observation, as far as concerns the head; but he was so idle and so unambitious that the remainder of the picture, except sometimes the hand, was commonly copied from some print after Sir Godfrey Kneller. Some of his pictures are very fine and many more good for nothing, though the worst of them still look like the careless productions of a good painter." Sir Joshua said "he had seen portraits by him that were equal to those of Rembrandt." One of the precepts of Gandy was that "a picture ought to have a richness in its texture as if the colours had been composed of cream or cheese, and the reverse to a hard and husky, or dry manner." The remark was repeated to Reynolds, and how largely he profited by it is apparent from the circumstance that it would be difficult to describe more accurately the usual surface of his own paintings. The germ of his distinctive qualities may be clearly discerned in particular specimens of Gandy's works, but these merely furnished the spark which lighted up the latent powers of a far greater man.

The Hall, Hampton Court.

The hall formed no part of Cardinal Wolsey's palace, and its erection was not commenced until five years after the Cardinal had given up Hampton Court to Henry VIII., in exchange for the manor of Richmond. The manor of Hampton was granted to the Cardinal by the prior of the Knights Hospitallers of St. John Jerusalem, and the Cardinal commenced the building of Hampton Court about A.D. 1515. In June, 1525, Wolsey surrendered Hampton Court into the possession of the Crown. There is conclusive evidence that preparations were made for removing the "old hall," and laying the foundations of the "new" or present hall in 1531 (anno 22 Henry VIII.). Tilers, masons, carpenters and smiths were in full activity working on the "new" hall in the following year. In the twenty-fourth year the roof was raised. The progress of the works until the twenty-sixth year of Henry VIII. may be fully traced. After this year the entries refer rather to repairs than new erections and the building of the hall may be said to have been completed. The interior still retains most of its original features and ornaments, the pavement alone being excepted. If we may judge from a drawing made by Lysons, about 1800, the floor of the hall even then consisted of tiles—"paynted tyle ypared with poynttyl ich point after other." It is stated that Flemish paving tiles of green and yellow, at 5s. the hundred, were used anciently for the "hall pacys" in the queen's new lodging. This hall, like others in early times, was heated by means of logs of wood piled on a hearth in the centre of the building; the bright flames flashed against the rafters, and the smoke escaped from a cupola or louvre rising out of the roof. There are no remains of this fireplace, which was perhaps removed by Kent when he laid his profane hand on the hall. The restoration of the coloured glass throughout the hall was executed by Willement. The pedigrees of the six wives of Henry VIII. are set forth in alternate windows. The intermediate windows, seven in number, contain the heraldic badges of Henry VIII.

NOTES AND COMMENTS.

MUCH may be forgiven to the young artists of Paris when they find they have to reside in a city which is no longer favoured by the clerk of the weather. But there are limits to joking. Because it is not possible to take a turn in the streets students should not take revenge on the scavenging department of the Municipality by endeavouring to make artists like M. CAROLUS DURAN, M. RODIN and M. PUVIS DE CHAVANNES appear ridiculous. The dinner which was given to the last-named by his friends and admirers was made the occasion. Circulars were printed and circulated among artists. In one they were solicited to join in a dinner to M. CAROLUS DURAN, in the other M. RODIN was named as the honoured guest. The grounds for the festivals were parodied from the invitations to M. PUVIS DE CHAVANNES'S friends. We understand that similar announcements were made of dinners to other artists, but the intended victims are silent about them. In each case the letters were supposed to be issued by a special committee. Like all the other practical jokes of the young artists during some years, the latest will give rise to pity rather than amusement.

THE director of the South Kensington Museum, Mr. J. H. MIDDLETON, D.C.L., has acted wisely in resolving to abstain from seeking re-election as Slade Professor at Cambridge. His official duties should be onerous enough to occupy any man's time. The election of a substitute will therefore take place on Monday, February 25. The professor is elected for three years, but is eligible for re-election. The stipend is about 348*l.* per annum. The professor is not required to reside, but must deliver annually in the University in full term a course of not less than twelve lectures on the history, theory and practice of the fine arts. The electors are the Vice-Chancellor, Professor JEBB, M.P., Dr. PEILE, Master of Christ's; Dr. SANDYS, the Public Orator; the President of the Royal Academy; the President of University College, London; and Sir A. W. FRANKS. Candidates are to send their names to the Vice-Chancellor on or before February 18. It is time a more definite notion should be arrived at about the duties of the professors. At one time it might be supposed they were to be directors of art classes; at another time they are assumed to be only lecturers. The best type of professor was the late Sir DIGBY WYATT, for he was competent to deal with history, theory and practice. The electors would do well to seek after a gentleman who was as versatile and as engaging.

SOME months back it was announced that several schools were not in a fitting condition to receive children, and unless repairs and alterations were undertaken, the Education Department would be compelled to withhold the grants. In the three last months of 1894, the authorities of no less than twenty-six schools were served with the official warning. The names of the schools cannot be too widely known. They are:—Waddesdon (British), Buckinghamshire; Falmouth (British); Derby (St. Alkmund's National); Little Totham, Essex; English Bicknor (National), Gloucestershire; Leinthall Earles (Church of England), Herefordshire; Stoke Golding (infants), Leicestershire; Eastville, East Fen, and Fosdyke (both Church of England), Lincolnshire; Peckham (Wesleyan), London; Tottenham (Wood Green, Naas Road Board); Newcastle-on-Tyne (United Methodist Free Church); Bridgnorth (Roman Catholic) and Ludlow (Wesleyan), Shropshire; Saltford (Church of England), Somersetshire; Wolverhampton (Causeway Lake National); Lewes (British), Sussex; Allerton Bywater, Austerlands, Darton (Beaumont's Charity), Hull (Christ Church and St. Luke's), Kelbrook, Newton, Rawmarsh (High Street), and Wakefield (Trinity), all of which are National or Church of England schools in Yorkshire. A London Board School in Bailey's Lane, Upper Clapton, and Clifton Church of England School, Lancashire, have been suspended for three months or more on account of defects in the school premises. In some cases there may be extreme poverty, but as we said

on a former occasion, there are wealthy people who profess to take a special interest in all schools of the class, and now is their time to display liberality. Another instance of departmental watchfulness has been shown during the week. As the schools are now utilised for public purposes of another kind, it is advisable to know whether precautions are taken to minimise the effects of a panic in case of fire. The inspectors of schools are therefore told they are to strongly advise that all doors should be made to open outwards, and that they should be sufficient in number and size to provide for the speedy exit of those who are in the room. In large schools at least two separate exit doors are most desirable; in small schools one may be sufficient. It is not to be expected that school buildings are sufficiently elastic for adaptation to a variety of purposes for which they were not planned. The Parish Councils Act has made public buildings for meetings indispensable throughout the country, and the sooner that provision is insisted on the more efficient will be the provisions of the Act.

THE spirit of the proverb which affirms that it is not right to look in the mouth of a horse which is a gift we suppose should be respected when the gifts are works of art. Pictures ascribed to great masters abound in this country, and are often to be acquired for less than the value of the frames; but is it always wise to purchase them? The late Mr. W. RAWDON has bequeathed to the City of York a number of pictures which he believed were of value in a financial as in an artistic sense. They include, according to an inventory:—*A Holy Family*, by RAPHAEL; *Venus and Adonis*, by TITIAN; *The Doctor's Shop*, by TENIERS, sen.; *The Spanish Guardhouse*, by TENIERS, jun.; pair of portraits said to be *George III.* and *Queen Charlotte*, by HOGARTH; *Child and Dog*, by GREUZE (an unfinished picture); *Teaching the Bird to Sing*, GERARD DOW (portrait of artist by himself); *The Sick Lady*, by VAN GOYEN; two Dutch landscapes, with figures, by BREUGHEL (painted on copper); and *Woman Blowing a Candle*, by SHALKIN. Now, if all these works were genuine York would have gained an additional attraction. But how is the genuineness to be proved? Will the Corporation, before accepting the pictures, employ experts to examine them, and if their report is doubtful, will the pictures be retained? An individual may purchase as many RAPHAELS, TITIANS, and GERARD DOWS as turn up in the course of a few weeks in London; but in a public gallery we expect to see nothing that is not authentic, and if there are doubts about Mr. RAWDON'S pictures they should be returned with thanks to the executors.

FROM the annual report of the Wesleyan Chapel Committee it would appear that the outlay on buildings during the past year has been 288,055*l.* The accommodation has been increased by 19,885 sittings. The debt remaining amounts to 82,693*l.* The committee have sanctioned 373 cases, 90 of these being new chapels, 48 of which are to be erected in localities where hitherto Wesleyan Methodism has been unrepresented. The estimated outlay is 199,761*l.*, of which amount 141,963*l.* is to be raised by voluntary contributions. The total additional accommodation to be provided is 14,954 sittings.

A FIRE on Wednesday morning caused irreparable damage to the Municipal Buildings in Perth, of which the late ANDREW HEITON was architect. It was only last week we published a view of the council chamber. It is too early to be able to state the cause of the fire, but it is understood that a flue on the ground floor was overheated, and the fire commenced in the police office. It then extended to the court-room and commissioners' hall. The latter was destroyed, with its pictures and statues, besides windows which illustrated scenes from SCOTT'S "Maid of Perth." The municipal documents, it is understood, were saved. The building was so successful, it will probably be restored from the plans which were originally employed in constructing it.

THE HISTORY OF CLOVIS.—NO. IV.

AFTER the victory of Tolbiac CLOVIS kept his promise, and was baptized by St. REMIGIUS, the Bishop of Rheims. If we assume the date of the ceremony as A.D. 496, it would appear that M. BLANC has represented the prelate as too young. It is true that according to tradition REMIGIUS was appointed a bishop at the age of twenty-two, but that event took place in A.D. 457. It has been assumed that CLOVIS changed his religion through policy. According to THIERRY, CLOVIS was among all the early Frankish kings the nearest to a statesman. It was in order to found an empire that he rejected the worship of the Northern gods and became the associate of the bishops in destroying the two Arian kingdoms which were found in France. But as became a warrior of that age he was often more impulsive than subtle. GIBBON tells us "the mind of CLOVIS was susceptible of transient fervour; he was exasperated by the pathetic tale of the passion and death of CHRIST; and exclaimed, 'Had I been present at the head of my valiant Franks I would have revenged His injuries.'" The conversion of the leader was not followed by an immediate change in the character of himself or his followers. The legends attest that CLOVIS was often obliged to recognise the obstinate attachment to paganism of his chiefs. Nor were his own actions always in keeping with Christian morality. It is, however, unwise to consider the character of the individuals of the fifth century too closely. CLOVIS, with all his crimes, was an agent who helped to promote the civilisation of the northern barbarians. He led them to France, and although they conquered the Roman colonists, they were in turn overcome by their works. The influence of architecture on the wild tribes is too generally ignored, but it has been upheld in one of GUIZOT'S most memorable passages:—

What now moves ourselves, what we seek with eagerness in history, poems, travels, novels, is the representation of a society foreign to the regularity of our own. It is the savage life, its independence, novelty and adventures. Very different were the impressions of the barbarians; it was civilisation which struck them, which seemed to them great and marvellous. The remains of Roman activity, the cities, roads, aqueducts and amphitheatres, all that society so regular, so provident, and so varied in its fixedness—these were the objects of their astonishment and admiration. Although conquerors, they felt themselves inferior to the conquered. The barbarian might despise the Roman individually, but the Roman empire as a whole appeared to him something superior; and all the great men of the age of the conquests, the Alarics, the Ataulphs, the Theodorics, and many others, while destroying and throwing to the ground the Roman empire, exerted all their power to imitate it.

For CLOVIS was, like CHARLEMAGNE and NAPOLEON, a legislator as well as a warrior. An attempt was made by the chiefs of the Franks to codify laws and customs, and the result was known as the Salic Law. According to one of the old jurists, "when CHLODWIG (CLOVIS), the long-haired, the beautiful, the illustrious, had received baptism, everything in this covenant that was considered unfitting was amended with perspicuity." THEODORE, the son and successor of CLOVIS, was also zealous in applying system to law.

By the force of laws and arms CLOVIS was able to overcome the Armoricans, the Burgundians and the Goths. The whole of Gaul was under his sway. Yet, such was the power of sentiment in that age, CLOVIS did not believe he had attained the summit of ambition until he received the dignity of a Roman Consulship, which was no more than a name, a shadow, an empty pageant. But policy may have dictated his desire to become affiliated to Rome. As GIBBON says, the Romans in Gaul "were disposed to revere, in the person of their master, that antique title which the emperors condescended to assume; the barbarian himself seemed to contract a sacred obligation to respect the majesty of the Republic, and the successors of THEODOSIUS, by soliciting his friendship, tacitly forgave and almost ratified the usurpation of Gaul."

If CLOVIS had a weakness for burning the Romanesque churches of the Arians in Gaul he made compensation by erecting others for orthodox Christians. A church dedicated to SS. PETER and PAUL, which stood on the hill

outside Paris, was one of his works. It was afterwards supplanted by the church of St. Geneviève. The church and abbey of St. Pierre de Chartres and the abbey of St. Mesmin, near Orleans, may be mentioned also. One of his sons erected the abbey of St. Vincent, subsequently known as St. Germain des Prés, in Paris, and it is believed some of the ancient masonry still remains.

INTERIOR OF THE REDEMPTORISTS' CHURCH, PERTH.

HIGHER GRADE AND TECHNICAL SCHOOLS FOR THE DOUGLAS SCHOOL BOARD, ISLE OF MAN.

THESE buildings have recently been erected on a site fronting Park Road, Douglas, and provide accommodation for 550 scholars.

The buildings, which are two storeys high, are constructed of local grey pressed bricks, relieved by red-pressed bricks, the heads and cills of windows, &c., being red sandstone.

The classrooms on both floors are accessible from a marching corridor 9 feet wide, which is tiled, and has a dado 4 feet high of salt-glazed bricks. Separate entrances, lavatories and cloak-rooms, staircases, &c., are provided for the girls and boys.

On the ground floor, adjoining the boys' entrance, are arranged a head-master's-room and assistant master's-room; adjoining the girls' entrance are a female assistants'-room, with lavatory, &c., and a stationery store-room.

The lavatories and cloak-rooms are tiled, and are lined with white-glazed bricks.

On the first floor are arranged a chemical laboratory, lecture theatre, cookery classrooms, special art classrooms, &c.

The chemical laboratory has accommodation for thirty-six students, and is replete with every modern convenience, demonstration platform, fume closets, store-room, &c., and was fitted by Mr. THOMAS STORY, of Leeds.

The seats of the lecture-theatre are arranged in circular tiers, and accommodate seventy-two students.

The cookery classroom has tables, a kitchen range and gas cooking range, scullery, store-room, &c., and has accommodation for twenty-four students at practice and seventy-two at demonstration.

The classrooms throughout have a pitch pine dado 4 feet high, and are well lighted by left hand light, and are provided with STOTT'S patent ventilating sunburners. The heating is by means of SHORLAND'S ventilating grates and hot-water radiators.

The corridors, &c., are heated by low-pressure hot-water pipes and coils.

Separate asphalted open and covered playgrounds and latrines are provided for the girls and boys.

Over the boys' covered playground is arranged a joiner's workshop, with lathe, &c., and bench accommodation for sixteen students.

The contract has been carried out by Messrs. MCADAM & MOORE, contractors, Douglas, for the sum of 4,140*l.*, from the designs and under the superintendence of Mr. THOMAS W. CUBBON, architect, Birkenhead, whose designs were selected in a limited competition.

DOWNSSELL ROAD BOARD SCHOOLS, WANSTEAD.

THIS building, which will shortly be completed, is situated on the detached part of Wanstead known as Wanstead Slip. The western portion of the school, consisting on each floor of three classrooms and a school-room with lavatories and staircase, was erected in 1886; two more classrooms on each floor were added in 1888, and the plans for the completion of the building were sanctioned by the Education Department a few weeks ago. Externally the building is faced with picked stocks and kiln-burnt red bricks; internally also picked stocks are employed above the brown salt-glazed brick dado. When completed the school will accommodate about 1,800 children, and will have cost about 15,500*l.* The two earlier portions of the school were built by Messrs. A. REED & SON, of Burford Road, Stratford, E. The architect is Mr. JOHN T. BRISSEY.

THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Association was held on Friday evening, Mr. E. W. Mountford, president, in the chair. Mr. R. A. S. Macalister was elected member.

It was announced that the first spring visit would be paid to the Church House, Dean's Yard, Westminster, where probably Sir Arthur Blomfield would meet the members.

Mr. JOHN SLATER read the following paper on

Bricks and Brickwork.

The history of the development of the human dwelling, if worked out thoroughly in a scientific spirit, would not only be a subject of the deepest interest to all who have to do with modern buildings, but would clear up many of the knotty points upon which archæologists have never been able to agree. The first rudiments of building were undoubtedly the cutting down and joining together of substantial pieces of timber, and as men grew more expert in the use of their rude implements, simple patterns would be cut in the timber, the repetition of which would form a band of ornament, and we should have the commencement of a timber style of architecture.

In China and Japan such a timber style has survived with the growth of civilisation, and very picturesque results are obtained from the elaborate carvings and decorations with which these buildings were enriched. But, as a rule, with advancing intelligence and manual skill, and with the discovery of the use of metals, men would not fail to contrast the ephemeral and destructive character of their timber dwellings with the hard, dense and apparently imperishable nature of the rocks and stones which formed the everlasting hills which they saw around them. And you must remember that, although no means of quarrying then existed, nature herself is the most efficient quarryman. Water and frost, heat and cold will in the course of ages break up into manageable sizes the hardest rocks, and I do not think there can be a doubt that the earliest stone buildings were formed of rough pieces of rock picked up haphazard and roughly fitted together, the interstices being filled in with some softer materials, such as clay, earth, or sand. Anyone who has examined the remains of the early British villages which exist in many parts of Cornwall, or the very interesting chapel of St. Piran in that county, which dates from the seventh century, cannot fail to be struck by the fact that, as far as the walls are concerned, the stones had no work on them at all, and were simply brought to the spot just as they were found on the hillside and placed in position as they happened to fit. The probability is that the first enterprising tribesman who built himself a stone dwelling would run the risk of having it pulled down about his ears by his neighbours for his presumption, but gradually his example would be followed, and we should have the rudiments of a stone architecture. But in many places as the population increased communities would settle down in districts where no stone existed and where the soil was chiefly of clay. Here the enterprising builder would find no hard material ready for his use, but he would notice how in summer this clay became exceedingly hard when the sun beat down on it, and the ingenious man would one day be struck with the idea that if he could dig up lumps of clay when it was soft, of a size that could easily be carried, and let the sun harden them, he would be able to transport them where he liked and use them to make a house with; and in this you have the first beginning of a brick architecture.

The use of unburnt, sun-dried bricks dates back to a hoary antiquity; they were made and used for all kinds of building in Egypt; Greece, where the palace of Cræsus and that of King Mausolus were thus constructed, Assyria and Persia, and in hot, sunny countries they are still used to-day. Chopped straw was mixed with the clay in order to give it a consistency, and where very little rain fell these bricks answered fairly well. In fact, they formed the principal material with which the enormous and elaborate Ninevite and Babylonish palaces were constructed. If not very carefully tempered, these sun-dried bricks soon become very friable; and it is owing to this fact that of the majority of these wonderful cities of the East which we read of in history, nothing now remains but a heap of earth and rubbish. But it is also to the fact that the rubbish appeared absolutely valueless that we owe some of the most interesting discoveries of recent years. Wherever any old stone buildings existed that became ruinous or deserted, the neighbouring inhabitants invariably used them as a quarry and carried away the stone for their own use; but in Assyria no one ever thought it worth while to cart away crumbling clay and earth. Some few years ago a Frenchman named Botta obtained the requisite permission to excavate one of these huge mounds in the desert, with only a few straggling huts around it. His explorations were continued by M. Victor Place, and the result was most unexpected, and showed that many of our architectural forms and features have a much greater antiquity than anyone imagined. One can easily understand that in a clay district it would soon become apparent that artificial heat,

such as might be obtained from a cooking-place, hardened the clay and altered its colour, but few can have imagined the use that was made of the knowledge of this property in the clay for the production of decorative effects.

These excavations took place about 12 kilomètres from the Tigris, at a little village the modern name of which is Khor-sabad, which is on the site of the great palace built by King Sargon. Buried under the *débris* of centuries was found a walled city with fine gateways, the palace itself with a magnificent arched gateway of brick, the voussoirs being carefully moulded to the proper shape and enamelled in various tints, forming a beautiful pattern, and as vivid as if they were lately taken from the kiln. Artificially burnt bricks used for paving, and so hard that when struck they rang like a bell, and the discoverers used them as paving for the floor of their temporary stables; arched covers for sewers formed of radiating bricks accurately moulded, and glazed wall-tiles in profusion were discovered. The sizes of the bricks varied considerably, the paving bricks being about $15\frac{1}{2}$ inches square and $2\frac{1}{4}$ inches thick, and these were carefully laid in two courses, breaking joint; their colour was a dull red, approaching brown. The arch-bricks in the conduits or sewers were curiously formed, every alternate course having a keystone of peculiar shape, and M. Place's belief is that the intervals were keyed with ordinary unbaked bricks, thus affording, in case of repairs being required, an easy means of entering the sewer. The height of the walls of the palace was about 15 mètres, or 49 feet, and their thickness 5 mètres, while the height of the encircling wall of the city itself was about 23 mètres, and the thickness nearly 8 mètres. The gateways, both of the city and the palace, were of such a kind as one would never have expected, being true arched openings about 14 feet in width and 21 feet high, the arches being formed of four rows of bricks very carefully laid, with radiating joints. It is a most extraordinary thing to find these old Assyrian builders planning and executing so fine a work as this. There is one peculiarity about these glazed bricks: although their colour was perfect and the bricks themselves uninjured, they were comparatively soft, and the part built into the wall could be dented by the mere pressure of the hand.

Although, as I have stated, bricks were used in Greece, yet the abundance of excellent marble in that country prevented builders having recourse to an artificial material. In Rome, however, and her colonies brick was extensively used, although recent investigations have shown that many of the old Roman buildings which were supposed to be erected of solid brick are really only brick-faced, and that the interior of the walls is concrete of the most admirable kind. Apart from this, however, there can be no doubt the Romans were excellent brickmakers, as is evidenced by the present condition of many buildings which were erected in various parts of Europe and this country during the Roman occupation. Take the Basilica at Trèves, for instance, nearly the whole of one side of which is the original brickwork, as well as the lofty arch between the apse and the main body of the building, and if you examine it carefully you will see that there was no scamping in that work. The excellence of Roman bricks is further shown by the fact that in many parts of this country what are undoubtedly Roman bricks that have been taken from some vanished building and reused in other places, are still found in an unimpaired condition of strength. St. Albans Abbey may be mentioned, where such bricks occur in large quantities, Dover Castle and many other places. It may be interesting to notice the size of Roman bricks, which are chiefly remarkable for their length and thinness. Vitruvius enumerates three kinds of bricks: the pentaduron, $14\frac{1}{2}$ inches square and $1\frac{1}{4}$ inches thick; the tetraduron, $11\frac{1}{2}$ inches square and $1\frac{1}{4}$ inches thick; and the didoron, $8\frac{1}{2}$ inches by 5 inches by $1\frac{3}{4}$ inches, the two former being used chiefly in Greek buildings, and the latter in the Roman buildings of his time. The size of Roman bricks varies considerably; at St. Albans they are found 18 inches by 12 inches by $1\frac{3}{4}$ inches, in the old London Wall $17\frac{1}{2}$ inches by $11\frac{3}{4}$ inches by $1\frac{1}{4}$ inch, while I myself have measured some in Colchester Castle about 15 inches long and barely 1 inch thick. After the close of the Roman dominion, brickmaking, as well as nearly all other arts and sciences fell into decay, and it is a curious fact that, whether in the British Isles or on the Continent, we have very few remains of any brickwork that is not Roman until about the thirteenth century. St. Sernin, at Toulouse, a church of the twelfth century, is partially built of brick, but the convent of the Jacobins at Toulouse, dating from the end of the thirteenth century, is one of the finest examples of brick building in the Middle Ages. As Viollet-le-Duc points out, it is in this part of France that good building stone is entirely wanting, and consequently the architects of the time were compelled to elaborate a style of their own in the only available material, brick. In the thirteenth, fourteenth and fifteenth centuries French bricks were of large size, about 13 inches by $9\frac{3}{4}$ inches by $2\frac{1}{4}$ inches, and the mortar joints were frequently within a fraction of an inch as thick as the bricks themselves. Moulded bricks are but rarely met with, but cut brickwork of very interesting character is found much oftener. It is clear

to my mind that Viollet-le-Duc, with all his wide knowledge and versatility, held brick architecture in somewhat low estimation, for two pages in his *Dictionnaire* dispose of the subject.

In Germany you will find brick largely used in those districts where stone is poor and scarce, but the general mode of treatment in that country is somewhat heavy and uninteresting. There are, however, many fine examples. The Marien Kirche at Lübeck, dating from the end of the thirteenth century, is one of the best specimens of German brick architecture, and this church had a great influence on the style of the surrounding parts of the country. At Brandenburg on the Havel is the fine church of St. Catherine, late fourteenth century, which has one of the most elaborately ornamented exteriors of any brick edifice. I have some diagrams of characteristic German brickwork. One is a gable from Thorn, which is an old fortified town in North-East Germany, on the Vistula. Another is a window from a church at Dobrilugk, a small town on the line from Berlin to Dresden; the third is a mullion of one of the windows of the church of SS. Mary and Nicholas at Frankfort-on-the-Oder. At Preslau, on the Uckersee, is the very fine Gothic church of St. Mary, dating from 1340, but now restored; and there is one from Seebausen. I have noticed one peculiarity in modern brick buildings in Germany, which is this—the joints are left raked out for a depth of about half an inch from the face of the work as if for pointing, but no pointing is inserted. In appearance the effect is not bad, but I should think it must increase the tendency of wet to soak through the walls.

In Spain—my acquaintance with which country is as yet, I regret to say, confined to second-hand knowledge—brick was used extensively and effectively in the Middle Ages, though in a manner quite distinct from that which prevailed in other parts of Europe. Mr. Street has little doubt that by far the larger part of the brickwork in Spain was done by Moorish workmen, who retained their old constructive traditions. The special peculiarity of Spanish brickwork seems to be that it was rarely moulded, and effect was obtained by simple projections, as at Zaragoza, where patterns are formed by setting forward the bricks forming the outlines from $1\frac{1}{2}$ inches to 2 inches beyond the general face of the wall and filling up the spaces with a diaper of small tiles. All the Spanish bricks are narrow—a little over $1\frac{1}{2}$ inches thick—and the mortar joints are half an inch thick. The Torre Nueva, in the same city, used to be one of the very finest specimens of brick architecture, octagonal on plan and the faces covered with diapers; but, unfortunately, as you are probably aware, this most interesting relic of the Middle Ages has very recently been taken down because of its leaning so much out of the perpendicular. At Toledo the churches of San Roman and Santa Magdalena are excellent examples of the simple and proper use of brickwork. One of the diagrams shows the campanile of this church. The construction is rubble stone with string-courses and quoins of bricks perfectly square and with very thick mortar joints. As I have for some time had a great distaste for what is called gauged brickwork, where the bricks are rubbed down and set in putty with as fine a joint as can be made, Mr. Street's opinion on the effect of these thick joints is gratifying as well as interesting. He says of Santa Magdalena:—"The bricks are used very roughly and picturesquely, with a very thick mortar joint, and the consequence is that every part of this work has a value in texture and light and shade undreamt of by those who have never seen anything but our own smooth, smart and spiritless modern brick walls, built with bad bricks and no mortar." And he goes on to say, in a note, "I am aware that, in saying this, I blame myself as much as any one else."

The Netherlands are rich in brick buildings, and I know nothing much more interesting than a ramble through the narrow streets of some old Flemish city where each house seems to try and outdo its neighbour in the quaintness and originality of its steep brick gables. Picturesque, however, as these are, they always strike me as somewhat wanting in grace and refinement. They are the honest and often successful efforts to escape from monotony of a somewhat rough and uncouth race, whose exuberant genius was unrestrained by any knowledge of or love for proportion such as is shown in Classic architecture. The general effect is quite charming, and we, who are accustomed, in the majority of our English cities, to the horrible monotony of a straight skyline formed by a parapet which completely conceals the roofs, can readily forgive the quaint fancy which ran riot in these stepped gables; but the detail is often unsatisfactory, and it is not till we visit North and Central Italy, where the Roman genius and Classic traditions had lingered longest, and where the strength of the northern Gothic was restrained and curbed by the southern love of colour and refinement, that we find the highest development of a brick style in architecture, and an examination of these buildings will, I think, effectively dispel the notion which some people used to be so fond of holding, that brick is a vulgar and inferior material, unfit for use in a large monumental edifice. Street's volume on "Brick and Marble in North Italy" came nearly forty years ago as a revelation to

many, and the swing of the pendulum which, during the last few years, has sent Gothic art out of fashion and has brought to the fore a style which, with all its merits, appears to me to carry in itself the seeds of its downfall and decline, as surely now as at the time of its first inception, in that lack of reserve and striving after the *outré* and the fantastic which speedily swamped what was true and good and beautiful in the Renaissance, and led to all the monstrosities of the Rococo—this late rebound, I say, may very probably have prevented the student of the present day from giving that attention to the Gothic architecture of North Italy which it well deserves. Personally, I know of no more delightful field of study, and can only regret that circumstances have not allowed me to visit it more frequently. The lovely variety of tint of the mingled brick and stonework, the juxtaposition of the circular and pointed arch, and, above all, the charming simplicity with which the most beautiful effects are produced, all combine to make the brick architecture of this district unequalled in attractiveness.

Take Verona, for instance—the city which lives in my recollection as the most picturesque in its surroundings and the most interesting in its buildings of any that I have ever visited. The first thing that strikes the eye here is the noble campanile which rises from the group of buildings at the corner of the Piazza dei Signori to a height of nearly 320 feet, though its lower part is concealed by surrounding buildings. It is built at first in alternate courses of brick and stone and then wholly of bricks. For more than half its height it is quite plain, entirely without buttresses, and pierced by three or four small openings only, and then there is a belfry stage, above which is an octagonal storey of later date. The belfry windows are contained under a large pointed arch, and are divided into three lights, with coupled marble columns, the voussoirs of the arches being alternately of brick and stone. Verona is absolutely full of objects of interest, but I can only mention a few as illustrating my subject. The cloisters of the church of San Zeno are, to my mind, some of the most beautiful I have seen. The arches are of brick pointed on two sides of the quadrangle and round on the other two, and on one side is a small projecting arcade; they are without mouldings, and are supported on coupled columns of red marble.

The arcading of San Fermo Maggiore may also be mentioned; and strolling along the narrow streets of the city numerous interesting bits of brickwork will be discovered. There is one special characteristic of the treatment of brick and stone in Verona, namely, the introduction of narrow courses of bricks between the arch stones and the plain walling, or between two rings of voussoirs. This serves to accentuate the arch and to keep it distinct from the main body of the wall, and is an effect that might well be imitated in our own buildings. Venice, which of course has a charm all its own, is not very rich in examples of brickwork—or rather, perhaps, I should say that the examples are not of such excellence as in other Italian cities. The church of the Frari is one of the most interesting examples, and there are one or two early campaniles in brick, San Giacomo, del Rialto being the best. San Giovanni e Paolo, or Zanipolo, as it is called, has an elaborate cornice. It would be both easy and interesting to devote some time to the description of other Italian cities, such as Brescia, Mantua, and especially Cremona, but these would almost demand an evening for themselves; but there is one Italian city which must not be passed over, as it is built entirely of brick—I mean Bologna. The first view of its heavily-arcaded streets is undoubtedly somewhat depressing, but the student of brickwork will find any number of most interesting details. The magnificent church of San Petronio is almost entirely of brick, both inside and outside, and is most impressive from its grand proportions and the excessive simplicity of all its details. There can be little doubt that this church exercised considerable influence on Street, as is shown in some of the late churches which he built. But it is for its domestic work that I think Bologna most interesting, as it shows us with how little trouble and expense we can increase the architectural effect of our plain brick buildings. The brick cornices and corbel tables show any amount of variety. With these few and very inadequate remarks I must leave the subject of Italian brickwork, strongly advising everyone who has not yet done so to take the earliest opportunity of making acquaintance with it, or if that is impossible at first hand, to study Street's book on it.

In our own country, after the Roman occupation terminated, very little seems to have been done in brick until the fifteenth century, although there is one building—Little Wenham Hall in Suffolk—which dates from the end of the thirteenth century. The bricks here are interspersed with stone and flint courses, and they are of widely different shapes and sizes, and when I visited the building a few years ago with a few architectural friends, we came to the conclusion that it is very probable the bricks were not made purposely for the building. In the Eastern Counties bricks were largely used during the fifteenth and following centuries, one of the finest examples

being Layer Marney Hall, Essex, which has been frequently illustrated. Who was the architect of this building is not, I believe, known, but he was certainly a man of considerable ability, and, I am disposed to think, familiar with some of the Italian terra-cotta work, as not only in the main building, but in the outbuildings also, there are several charming little bits of moulded brickwork. Sutton Place, near Guildford, is a beautiful example of brickwork; but here the influence of Italian Renaissance is manifest, and there can be little doubt that Italian workmen were employed on this building. The detail is pure, the ornament refined.

In Queen Anne's reign English brickwork was under the full domination of the Renaissance, and truly wonderful was the result. As far as workmanship goes, it was admirable. Pilasters, cornices, panels, swags, bunches of fruit and baskets, and, in fact, all imaginable detail was formed of cut bricks with an ingenuity and at a cost of labour that almost excites one's pity. I quite admit the charm of some of the older and simpler forms of this style that are met with most frequently in old country towns where age has given a mellowness to the work, and where nature has so often added to the picturesqueness by the creepers which have overgrown the exterior; but of the later developments of the original style and of the modern imitations of it, what can we say? I am aware that I am on somewhat delicate ground here, and I feel perfectly that my own opinion is a mere personal matter and worth no more than any other person's; but I can only say that much of the modern brickwork in imitation of the Queen Anne style fills me with horror and detestation. When I see pilasters tacked on to a front which not only have an exaggerated entasis at their sides, but come bellying out in front like the sails of a ship, they remind one of the fable of the frog and the bull, and the bricks seem swollen with conceit at having attained to a form utterly foreign to their nature. And it is this, rather than the ugliness, which I so strongly object to. Brick is a hard material, moulded and baked in a kiln, and moulded bricks seem to me perfectly legitimate; but surely the original baked surface is the most fitting to resist the weather, and if you go and rub and cut all the surface off, and then give the material a shape and form utterly foreign to its nature, you are completely reversing the practice of the Mediæval builders, who have left us the most magnificent examples of their skill, and who invariably gave to each material they employed the ornamental treatment which it was best fitted to receive. Much of this modern treatment of brickwork seems to me on all fours with, and just as reprehensible as, the practice which prevailed in the early part of the century in London houses, where we find a small porch carried by what appears to be a solid stone column of the Doric order, but which turns out to be constructed of wood bent to a circular shape and kept there with an infinity of trouble. In each case the material has been tortured, and bears on its face the imprint of its suffering. Having now given you a very rapid and incomplete *résumé* of the historical part of my subject I come to the second portion of what I have to say to you this evening, which relates to the actual materials with which our brickwork is constructed.

I do not think it necessary to occupy your time with any detailed account of general brickmaking, as you can get the information from the various text-books which treat of the subject. You know there are two main distinctions in bricks, viz. clamp-burnt bricks and kiln-burnt bricks; in the one case the fuel being mixed with the clay and all being burnt together, of which kind a London stock is an example; and in the other case the brick being formed of the clay, or rather the mixture of clays and sand and other ingredients—because it is quite exceptional to find a clay that of itself will make good bricks—and then being baked in a kiln, of which there are many different sorts. The thorough tempering of the clay, and mixing it well together, are very important points to be attended to. A very large quantity of brickmaking machinery is now in use, and a great deal of stuff that years ago would have been quite useless is now ground up and made into bricks, and the heavy machine-pressers give a smooth face to many a brick which is really not at all fit for use in a building, at any rate when exposed to the weather. You will often find that a smooth-faced pressed brick will flake off. I have particularly noticed this in the inferior kinds of white Cambridgeshire bricks and in those made near Hitchin and in that neighbourhood; and the reason is, I believe, that the outer layers of the bricks get more consolidated than the inner ones and a loss of homogeneity is the result.

The use of glazed bricks in buildings has very largely increased during the last ten years, and as I have myself been using a very large number in a factory which I am building, I took the opportunity last month of going over one of the large Leeds fire-brick works, and a short description of this kind of brick may not be uninteresting to you. The Leeds bed of fire-clay extends for a distance of six or seven miles only, and is associated with a thin seam of coal. The depth at which the clay is found varies from about 100 to 300 feet, and the seams are about 2 feet 6 inches thick. The following is an average analysis of the material,

and in the diagram on which this is shown I have put alongside it the analysis of an ordinary brick clay, that you may compare the two.

	Fire Clay.	Ordinary Clay.
Silica (Si O_2)	68.74	49.44
Alumina ($\text{Al}_2 \text{O}_3$)	18.94	34.26
Oxide of Iron ($\text{Fe}_2 \text{O}_3$)	1.45	7.74
Lime (Ca O)	0.19	1.48
Magnesia (Mg O)	0.03	1.94
Alkalies	0.05	5.14
Water	2.25	
Organic Matter	8.20	—

The clay, except where found quite near the surface, is almost as hard as rock, and has to be dug with a pick much in the same way as coal. The clay must be exposed for some time in the air to get thoroughly weathered, and then is sorted in order that all the particles of coal, ironstone and shale may be removed, as these spoil the brick. The clay is then crushed in a sort of mortar mill with a perforated bottom, having holes about one-eighth inch diameter. It is then taken to the tempering-pan, where water is mixed with it to the proper consistency. The tempered clay is then taken to the moulder who forms the brick, and then it goes to the drying-floors to stiffen. After that it goes to the presser and is very carefully weighed, because if one brick has more clay in it than another, the contraction during burning would be different and the sizes would not agree. It is then pressed in a small machine worked by hand and gauged and fettled up, and is soon ready for the dip. There are two kinds of material in which the faces of the bricks intended to be glazed are dipped; the first is called the body, and the other the glaze. Different firms have different recipes for body and glaze, but the materials used for body are Ball clay or blue clay, Cornish stone, flint, china clay, and plaster of Paris, in different quantities. These are calcined and ground to the finest possible trituration, mixed with water, and passed several times through a fine brass-wire sieve, having 120 meshes to the inch. The glaze is made of Cornish stone, felspar, flint, whiting, and plaster of Paris. After being dipped in the body the brick is left till the shine goes off in its face, and is then dipped in the glaze.

The materials which I have mentioned will give only an ivory or white brick; if other tints are required, such substances as oxide of cobalt, green chrome, bichromate of potash, or manganese are mixed with the glaze. Some stains, however, will not retain their colour in the heat required for a hard glaze, such as red and deep maroon, and in such cases the bricks are enamelled. In this process the enamel colour is mixed with a flux and ground together, and then, when quite dry, an oil formed of turpentine and resin is mixed with it, and the mixture is applied with a flat camel's-hair brush to the surface of the brick, which has already been dipped in body.

The bricks are then ready for burning, the kilns in which they are burnt holding from 18,000 to 20,000 bricks. Various coloured bricks may be burnt together, and experience shows what position in the kiln is best for the various colours. The glazed face must never be exposed to the flame. The kiln takes roughly about three days to burn and three days to cool, and uses about 25 tons of good coal. The brown salt-glazed bricks are made by simply throwing common salt into the fire when the bricks are burning. I am indebted to the Wortley Fire Clay Company, Leeds, for very kindly supplying me with the information enabling me to give you this short description of glazed-brick manufacture, and they have sent me up specimens of the stuff and the manufactured article.

To return to ordinary bricks. What is a good brick? Speaking generally, the characteristics of a good brick are:—1. Regularity of shape, so that when built into a wall the pressure is equal over its surface. 2. Toughness as opposed to brittleness, *i.e.* it ought not to snap when broken, but should require two or three hard blows. 3. Clearness of ring when gently knocked against another brick, and not a dull, heavy thud. 4. Homogeneity of surface and texture in the interior, and, above all, absence of small stones and pebbles or lumps of chalk; and 5, non-porosity, *i.e.* a slowness in absorbing water. I am very much disposed to think the latter quality the most important, and one that is perhaps least attended to—I mean, of course, with facing bricks. The rate at which a brick—or, for that matter, stone either—absorbs water is a more important element in its goodness than its total absorptive power, because when built in a wall the bricks are exposed only to intermittent wettings, and if in testing two samples of brick I were to find that one absorbed 15 per cent. of its volume of water in the course of an hour, while another absorbed 20 per cent., but took four hours to do it, I should prefer the latter. The crushing strength of a brick is an interesting subject of inquiry; but practically you will find it very rare indeed for bricks to be exposed in walls to anything approaching this crushing strain. Professor Unwin, at the Central Institution, Kensington, kindly tested some bricks for me a few months ago, and it was found that a Leicester brick

was crushed with a load of 245 tons per square foot, a Coventry brick at 217 tons, and a London stock at 125 tons, while a blue Staffordshire brick only cracked under a load of 385 tons per square foot, and could not be broken by the machine. A two-brick wall carried up 102 feet high, which is of course much higher than would ever be done in practice, would exercise a pressure of 5 tons per square foot on the lowest course, and this will show you how small is the chance of a brick itself being crushed; but a brick and brickwork are two very different things, the intervention of the mortar-joints introducing an entirely new element. Brick piers are very awkward things to experiment upon, and require very special machinery; but some practical experiments upon them have been made in the United States, and you may take it that three tons per square foot in mortar and five tons in cement are about the safe loads that should be placed on brickwork.

A gentleman whom I have not the pleasure of knowing has suggested to the secretary that it would be very instructive if I were to show some specimens of bad bricks, and point out how to find them out. The reason why some bricks in a clamp or kiln are good and others bad—irrespective of their position—is very difficult to understand even by practical brickmakers, but the most eminent firms are quite willing to admit that they do get a number of bad bricks, and one gentleman told me that out of a very large number of burnings his experience would lead him to the conclusion that 30 per cent. on an average were of inferior quality. What becomes of this 30 per cent.? One practical point is never to be guided in choice of a brick by colour alone, as it may frequently happen that what looks like an excellent brick may really be as bad as they make them. Knock them together and see how they ring—a bad brick will never ring well—and then break the brick and see its interior. If you see pebbles, or find the interior soft and not of close texture, you may safely condemn the bricks.

Underburning is, I believe, a fruitful cause of inferiority in bricks, as they are then soft and friable; and from my own observation I should say that, if you notice a load of bricks coming on to a job with a large number of broken ones among them, the chances are that the bulk of the bricks are bad ones, and they should be rejected. This is altogether apart from the risk to the work owing to the temptation to the men to use snap headers. To revert for a moment to the question of porosity. I believe if in an ordinary brick wall you were to pour water on the face at a level of about 6 feet from the ground, none of it would run down as far as the ground; the water would get absorbed before it reached so far, and this with very fair bricks. It may be of interest to you to know of an easy method of rendering a brick wall almost, if not quite, impervious to water. Wash the surface over with a solution of soft-soap and water, about half a pound to a gallon, laid on with a soft brush; and, when that has dried in, apply a solution of alum and water, mixed in the same proportions, and the result will be that you have waterproofed the wall.

It goes without saying, that however good your bricks may be you will never get good brickwork unless good mortar is used, and anyone who is in the habit of inspecting old houses will have noticed that in nineteen cases out of twenty it is the mortar which has perished and not the bricks. In fact, I believe a good brick is just as good after one hundred years' use as when it was new. I am sure the difficulty which public officers have with the speculating builder lies more frequently with the composition of this than with the bricks. The stuff which the "highly respectable building man" will endeavour to pass off as sand is of a fearful and wonderful nature. Sometimes he will use sand, but of such a soft, sugary texture, with no sharpness about it, that it is impossible for it to make good mortar. This you can test for yourselves by trying it between your fingers. But I should strongly advise you to look with the greatest suspicion on a heap of brownish grey stuff, which the builder will tell you is road sweepings. I am not saying that in country districts where the roads are mended with granite, if the road siftings lie in heaps for some months and are carefully washed you may not obtain a very good building material, but as a rule there is much organic matter in road sweepings, and it is very easy to mix garden loam with it, which is, of course, utterly unsuitable for mortar. Another thing that men will often try to use for mortar, especially for a building which is to take the place of one recently pulled down, is the siftings of the old lime and plaster which has come from the *débris* of the old houses. Sometimes you may spot this unmistakably by the smell, as I myself once did, a heap smelling very strongly of stale smoke from chimneys. As to lime, it is utterly impossible to discuss this question at the far-end of what I fear has been a terribly long infliction on you—it would take an evening to itself. I can only say I much wish it were more frequently the practice to build with cement-mortar. I am sure that cement and good sand mixed 5 and 1 would make better work than ordinary lime and sand mixed 3 and 1, and the extra cost would not be very great. There is one thing that you should be on your guard against in country districts—never

allow any brickwork to be built in chalk-lime mortar. It never sets in the interior of the joints. As to the joints, except in winter, I should always prefer to have the joints struck as the work goes up, rather than raking them out and pointing afterwards. There is always the risk of not raking the joints out far enough, and the chances are that the pointing will not adhere to the mortar in which the bricks are laid. Whether you have a struck joint or a pointed one, insist upon having it cut in at the top of the joint, and not at the bottom. The men will always do this if they are explicitly told to, but if not they will always cut it in at the bottom, why, I have never been able to understand, giving a lip on which the water collects. In hot weather you must be careful to dip the bricks in water before laying them, or they will absorb the water out of the mortar far too quickly, and prevent it setting properly.

One word in conclusion. In this country it can very rarely fall to our lot to be allowed to carry out a commission under those ideal conditions to which Mr. Brydon alluded last Monday evening in this room, when criticising the students' work at the Institute, viz. where cost is no object. Economy and utilitarianism are the conditions under which much of our work has to be carried out. We must often, therefore, be compelled to give up the use of stone and to fall back on brick. But do not let us on that account despise our material. It is a good honest material, which lends itself to an inexpensive decorative treatment of a perfectly legitimate kind, and I can only hope that in this short paper—the deficiencies of which I am fully conscious of—I may have given you some reasons for not neglecting the study of the history of brick in the past, and I am confident that such a study will be productive of nothing but good in its results on the brick architecture which you will have to construct in the future.

Mr. CLEMENT BROAD, brick manufacturer, Paddington, said that brickmakers were often at a loss how properly to supply architectural requirements. He referred to a specification that required selected stocks for one part of the work and picked stocks for another. Not knowing the difference, after careful consideration he supplied malm cutters, a soft brick. Competition and the system of close tendering was against the supply of good brickwork. Then he alluded to the various kinds of bricks in the market. From the same kiln were drawn shuffs, place bricks somewhat under-burnt, grizzels less under-burnt; next stocks, shippers, so-called because originally exported, and malms. Speculative builders were the best customers for the under-burnt bricks: whether they paid for the goods or not was a question. London stock bricks never decayed, contrary to what happened with some bricks from the Continent.

Mr. H. W. PRATT proposed a vote of thanks to Mr. Slater, and said that the lecturer had treated the subject exhaustively, both from a practical and an historical standpoint. For the substantial and enduring brickwork he preferred a wide to a thin joint. Sound-proof bricks for party walls were a desideratum, but he objected to the too pronounced weatherings so often seen in external brickwork.

Mr. F. T. W. MILLER seconded the vote of thanks. For the best brickwork he considered the universally adopted dimensions of bricks were not the ideal ones. The Roman form of bricks, much flatter, approached nearest the ideal of perfection.

Mr. OWEN FLEMING queried whether it was essential to put the best quality of bricks into internal walls. There was no undue crushing strain on internal brickwork.

Mr. S. BEALE disagreed with Mr. Slater in objecting to rubbed brickwork.

Mr. J. C. STOCKDALE expressed himself in favour of thin bricks for facing purposes, and recommended the use of salt glazed bricks, because they gave a pleasing variation of colour.

Mr. GARBUTT also supported the vote.

Mr. GOLDSMITH described the beautiful brickwork in Holland, which was flatly treated. In choosing bricks they should only rely on the actual results of their examination in the brickfields.

The President put the vote to the meeting, and it was carried by acclamation.

Mr. SLATER acknowledged the compliment, and the meeting adjourned.

A SYRIAN TEMPLE RUIN.*

IT is impossible to visit any of the ancient ruined cities of Syria without a feeling of interest which is intensified by a touch of sadness. The thoughtless traveller looks at the vast ruins, enormous colonnades, huge capitals rich in sculpture, and passes on with a wondering comment. The historian enters deeper into their meaning and they become to him the battle-ground of nation after nation. But to the artistic mind they are the records of a past grandeur and show us what we

* A communication from Mr. Charles A. Rich in the *American Architect*.

must have lost and of how much we have no authentic record in detail.

This thought struck me most forcibly in exploring Baalbek, whose ruins are among the most vast in Syria and of stupendous grandeur. I longed for a Pausanias who might have walked through the old city as he did through Athens, remarking carefully upon the visions of marble and statuary which I know must have stood on every hand, the votive offerings which must have lined the temple walls, the bronze, ivory or even golden statues, or better, giving us some glowing descriptions of the figures still standing in their niches, which might perchance have rivalled an Olympian Hermes or a beautiful Athene.

But no such good luck favours us, and we are obliged to rely upon imagination to people the temples with worshippers and the niches with their appropriate occupants; and yet, with all this lack of life and spirit in detail, Baalbek stands to-day the most interesting ruin in Syria. Oriental writers help us a little in the task, for they describe the ancient city as one of the most beautiful cities of Syria, enriched with palaces of great magnificence, monuments of artistic workmanship, temples of stupendous size and beauty, by virtue of its situation abounding in luxurious trees, and withal a city where, indolence being the result of wealth, studied enjoyment was the legitimate outcome and the natural pursuit of the people.

As I read these descriptions, six tall white columns rise up before my mind and carry me back to a little hotel window in the small village that surrounds the ruins of Baalbek. We had mounted a diligence at Beyruth, and, in company with the genial American consul, Mr. B—, had climbed the mountains which run far back of the Mediterranean seaport and disappear into the distant mist-surrounded snow-capped peaks. No more beautiful road could be imagined than this road over the Lebanon Mountains between Beyruth and Damascus. The road winds up and up in zigzags, which constantly change the view from the mountains to that over the sea away below, until at last, just before passing the brow of a hill which forms one side of the wild and romantic glen of Hummane, we come to a standstill and gaze in wonder at the glorious view. Mountains are on all sides, some snow-capped, and from these the breezes come cool and invigorating. Beyruth lies miles away and hardly distinguishable, and, beyond all, the Mediterranean Sea—a sheet of azure blue, on which specks reveal the presence of ships, but which ends at a soft horizon-line which marks the limit of vision.

In the glen below the little town of Hummane, which once sheltered Lamartine and gave the town its notoriety, nestles in a bower of plantations. We have clambered up 5,000 feet above the sea, and the scenery is wild and grand beyond description, and fragrant with the odour from the huge groves of trees which form the famous cedars of Lebanon.

When we have travelled thirty miles we approach the little town of Shtaurah, which consists of a few straggling houses and two hotels. The low archway of the smaller one is inviting, and a rude staircase winds up over the arch and gives access to a balcony on which stands a Syrian youth who smiles a welcome as we make our choice. The smile grows broader when we accept the welcome, spoken in French, for this lad turns out to be a student in his way, and has been mastering the idioms of the far away and, to him, unknown country.

Entering, we are assigned a large room adjoining the dining-room, whose windows open on the rear court and are at present occupied by a couple of the barn-yard fowl, who also bid us as good a welcome as their knowledge of language will allow.

Thinking to be forehanded in getting a carriage for the morrow to Baalbek, I told the young Syrian lad that we wanted the best team the proprietor could give us, but was dumbfounded when he said there were fifteen people ahead who were to take the large teams and mules, and that we would have to wait a day or so. "Not so," I confidently told him, "for whether anyone else has a carriage or not, I am bound to have the best one you have," and that the getting of it beyond the reach of anyone else meant just a midjidie (or a dollar) to himself. Verily the preacher was no traveller who affirmed that "the love of money is the root of all evil." The love of the dollar won us the day and our team besides; whether the "root of the evil" came to the boy after we had gone we never knew. At one o'clock in the morning the youth knocked softly at the door, laid out his scheme, received one-half his fee, the remainder to be paid when we should enter the carriage. It is needless to say we started early, before our neighbours were astir.

Upon turning off from the main road to Damascus the scenery changes completely. It follows through fertile plains skirting along the base of the Lebanon range. To stir up one's mind, add interest to the trip, and start up a sort of retrospection of time, we come to a building about 210 feet long, which the natives confidently assert is the tomb of Noah. What Mark Twain might have remarked at this point it is hardly possible to guess. Certainly, we argue with our driver, after the adventures of the Biblical mariner by sea, it would be

natural to seek some point away up high, back from invading floods, and, on the whole, tradition may be true. To look with distrust on anything the natives tell one is a sign of arrogance, and we are therefore happy to know that we have seen so remarkable a structure, and are careful also to let the native guide know that we are thus edified.

After several hours' travel away to the east, and at the foot of the Anti-Lebanon range, ruins can plainly be seen with the glass, and passing over the intervening plain we return to the vision which greeted our eyes as we looked out of the little window, and saw the grim acropolis of ancient Heliopolis, and the six white columns which stood out in the moonlight against the soft blue sky of a Syrian night. Almost under our windows, too, was the little circular Temple of Venus, where the goddess of youth and beauty, surrounded by her nymphs, was wont to bestow her favours in the licentious rites instituted by her admirers.

Such a night is enough to make the historian use all his powers to pierce the gloom that seems to envelop the early history and origin of the city which must have surrounded these ruins. But, although legend and tradition has been plentiful, no authentic data can be set down, although undoubtedly the city was known by some other name. Joshua speaks of the "city of Baalgad in the valley of Lebanon under Mount Hermon." This comes pretty close to a good description, but Hermon is fifty miles south of the present location, and this reference to a city 1450 B.C. does not seem to be tenable. Others have affirmed that it was constructed by Nimrod and his giants after the flood. Our guide believes it to be the oldest city in the world, and backs up his argument by the old tomb of Noah near by. His position stumped us to answer, for if old Noah's bones were laid where our good fellow affirmed that they were, it was just barely possible, yes, even probable, that he had planted the ancient city before us.

To Solomon also is ascribed the honour of its birth, since in 1 Kings ix. it is stated that "Solomon built . . . Baaleth and Tadmor in the wilderness . . . and in Lebanon." Now Tadmor is recognised as the city of Palmyra, and it is quite tenable to hold that the two glorious cities of Baalbek and Palmyra were referred to. The date then would be about 1000 B.C.

Such reasoning is easy, but the proof not authentic.

The more reasonable explanation of the name, however, has nothing to do with its ancient name, whatever it may have been. Baal was a recognised god, a deification of the sun, whose sanctuaries were erected in many pagan cities. The plain between Lebanon and Anti-Lebanon was known as Beka'a, and it is more reasonable to suppose that the name Baalbek simply signified that it was a city of Baal in Beka'a. And throughout the Græco-Roman period the city was referred to Heliopolis.

We have just come, however, from Egypt with its wonderful remains. We know that the Egyptians came into the land of Syria, and the Ramesseum at Thebes in its hieroglyphics states that the king journeyed thither and built huge structures and dedicated them to their gods. At Abu-Simbel, also, these expeditions are described minutely, and the districts pointed out correspond to the plain of Lebanon. The foundations of the chambers under the great Baalbek temple are constructed in the same manner as many in Egypt, and the general plan of substructure is much the same. I shall, therefore, beg to believe that Baalbek was made notable, if not founded, by the Egyptians, and furthermore that the old hero of marvellous works, Rameses II., is responsible for the above foundations and substructures of the Temple of the Sun. Surely the sun of such a people, the builder of such marvels of architecture in Egypt, might well have been their author.

Just as these Egyptian finger-marks are discernible in the substructure, so we are certain that the colossal platforms and the bevelled masonry under the peristyle of the Temple of Baal was of Phœnician work. And as we proceed with such deductions history begins to assist us, for we know that under Græco-Roman dominion the whole structure was reconstructed, Julius Cæsar formed a Roman colony, and the Temple of Jupiter and the Temple of the Sun were added to the already magnificent structures of the acropolis.

The ruins having been used by the Arabs as a fortress, parts of them have been built up high above the surrounding plain and form a veritable acropolis. To the eye, from the village, it seems threescore feet high, possibly, and the walls are encircled by a swift running stream, clear as crystal, near which are masses of tall trees with white trunks not unlike our native poplar. The tops just reach the temple platform, and the scene is exquisite and full of poetic feeling.

To the west the character of the work changes materially. Here are the cyclopean walls of the Phœnicians, which are the wonder of everyone who sees them, and call up the question of ancient methods of raising heavy stones. Six gigantic blocks of stone seem to form a sort of substructure to the work above. The stones are 30 feet long and about 13 feet high, cut with perfectly smooth faces, so carefully jointed that

the joint is hardly visible, and even in measuring these stones with the tape-line the joint is passed over by the eye. Above them, next come some stones which measure 64 feet in length and 14 feet in height. The old wall above these cyclopean stones was probably of Græco-Roman work, but it has been more or less pulled down, and all around are evidences of the rough work of Arab fortifications, consisting of column bases, friezes, capitals and bits of priceless detail.

In regard to the huge stones of which I have spoken, the quarry near by is interesting because there is one stone half cut out and left by the ancient builders. It is 69 feet 3 inches long and 14 feet square, and as we look at it we are caught questioning ourselves as to the resources of these unknown masters of past ages. To our modern eyes it would seem no easy task to construct lifting-machines for such weights, and true it is that no modern work has even been erected calling for such gigantic morsels. It is possible, however, that a recent discovery has given light on this point; it is at least an interesting addition to our knowledge. At Salkhat in the Hauran, which is that part of Syria beyond the Jordan, the fragments of an ancient lifting-machine have been discovered. The crumbling decay of ages and the corroding rust of metal has still left its traces on a simple gigantic lever, the fulcrum of which was supported on a huge tripod pedestal. Both of the members were composed of huge trees bound together with straps of metal, and the one found showed a height of 60 feet. The huge pivot was metal, and a large cage of iron chains and bars hung from one end while a gigantic grip was attached to the other end. Fill the cage now with small stones until it balanced the huge single stone, swing the lever around to the required position, and the work was accomplished and the puzzle solved.

But to return to the ruins. Passing around again to the east we enter the acropolis through a rough board gateway, at once plunging into the underground passages under the temple platform. Only a part of them are now open, but Roman inscriptions show that they were at some time occupied by soldiers, and were undoubtedly used as stables. Several hundred feet ahead a glimmer of light gives evidence of the exit on the court side, and on emerging the whole scene of ancient splendour is before the eye. It takes but the magic wand of imagination to fill out the picture. Back of us is the great court, on the right our six white columns, remnants of the Temple of the Sun, and on the left the Temple of Jupiter.

Walking directly east, passing through the great court, and thence through the hexagonal court to the pronaos, the limit of our survey in this direction is attained, for here is the façade of the grand portico of the Temple of the Sun. The broken wall, later built up to insure safety, shows stumps of the twelve columns of the pronaos, and originally a magnificent flight of steps gave entrance to the temple. The measure of this opening shows that the steps were about 150 feet wide, an enormous width, but not out of proportion with the tremendous scale of every part. It is interesting to note an inscription of Roman time on the bases of two of these columns. It was evidently a sort of artistic sop thrown out to the gods for protection, and gives a hint as to the decorative effect of the pronaos. "To the great gods of Heliopolis. For the safety of our Lord Antoninus Pius Felix Augustus and of Julia Augusta, the mother of our lord of the camp, of the senate of the country, Aurelius Antonius Longinus, chief of the First Antonian Legion, of his own free-will caused two brazen capitals of columns to be overlaid with gold at his expense."

The steel tape shows that this porch is 180 feet long by 137 feet deep, including the wings, before which were two Corinthian columns of exquisite detail, with niches and pilasters all around the chamber thereby formed. Statuary must have played an important part of this grand porch, for pedestals are seen on every hand. It would be interesting, indeed, if some of these could be unearthed in order to note their style and value. It is here indeed that we miss our Pausanias.

Three entrances next lead to a court 200 feet across, which, curiously enough, is hexagonal in form, a strange design surely, for the exterior angles do not conform themselves easily to chambers, as they are V-shape and unornamented by sculpture. But the four sides of the hexagon form chapels, as it were, each entered through a porch of four columns, the wall in the rear enriched with corbelled pedestals and niches for statuary.

Three more doorways next give entrance to the great court, and we here see some evidences of Egyptian influence, for on each side are semicircular niches with high stone flanks which are of the same shape and nature as the pylons of Egypt. The great court is totally different from any arrangement that we have seen. No continuous colonnade flanks the sides of the court, but, instead, there are on each side three recessed chapels, two with four columns and one with six columns, and between these chapels are two semicircular niches of exquisite design. The order of these niches is Corinthian, the entablature plain, with highly-enriched cornice, and the huge stones of the shell-like roof are, in many parts, perfect.

Below is a pilastered wall with pedimented niches which undoubtedly contained colossal statues, and it is obvious that the lower part of the wall was enriched with tablets. Traces of a basilica are seen in the centre of this court, and Constantine is named as its builder. Indeed, a huge base with raised platform is still seen, which gives evidence that a sacrificial altar stood there in the old days of paganism, and it was from the centre of this huge court that the smoke of the offering ascended and could be seen from the neighbouring country around.

We stand on this platform and look toward the west. Our six sentinel columns rear their exquisite forms against the blue sky, and the great platform of the Temple of the Sun stretches out with a vastness that is astonishing.

Think of the history that lies beneath those huge stones. For it was here that the great Phœnician Temple of Baal stood, and in its place later came the greatest and most exquisite temple-work of which history gives record. It consisted simply of a rectangular colonnade of fifty-four columns, without a cella. Whether it was ever intended to complete the walls within the colonnade is unknown, but if it was so intended it is strange that no foundation of such a wall can be found. A huge section of the entablature still remains *in situ* and shows what a profusion of ornamentation there must have been in the completed colonnade. The columns are 75 feet high in themselves and the entablature 14 feet higher. The shafts are 7 feet 3 inches in diameter, and the southern side of the colonnade fell outward, so that the huge drums lie like the vertebrae of some huge monster, dismembered but retaining their relative position.

Since the peristyle stood high above the courtyard and some 50 feet above the plain below, the effect from the distance must have been wonderfully impressive. Indeed it is so now.

One can hardly help wondering about the exact ceremonial that took place high up above the plain. Was there some huge stylus centrally located, upon which at a certain hour the rising sun fell and cast its mighty shadow upon the recumbent and reverent body of worshippers? Was there an offering upon the central altar whose fires were kindled daily by the concentrated rays of the sun god, who, rising, caused it to burst into flame and ascend toward the orb which gave it life? Or was there, as at Athens, some colossal statue of a deity standing enthroned in its glory, or through its priests giving out oracles of weal or woe from its capacious interior? The latter idea seems the most probable, as it was an old trick of the gods, known from one end to the other of the pagan priesthood; moreover, remnants of a secret staircase are discernible.

It is impossible to roam around over this area of elevated ground without thinking of the Athenian Acropolis. Here, as at Athens, was a town surrounding this central feature of religious life. In this case the elevated effect was gained partly artificially, while at Athens it was natural. But here, as at Athens, arose before the eyes of the people a grand central lesson, to which their thoughts daily turned, to enriching which their small means went, and to which they looked, in turn, for the favours of the gods. This similarity became the more apparent from the south, where, built up high above the stream below, stand the high walls of the Temple of Jupiter with many of the columns still erect. The temple is larger than the Parthenon, and being in the Corinthian order of architecture is richer, but the distant effect is not unlike that at Athens. It is the best preserved monument of Græco-Roman art in Syria, and is 227 feet long by 117 feet wide.

We climbed around to the east, this being the original entrance, and here, too, are the ruins of a flight of steps seen in a hole of excavation, for the *débris* of ages has filled in around it so that its base cannot be seen. Climbing up on a pile of stone and broken drums a nearer view of the detail is obtained. The entrance must have been of wonderful beauty, for the profusion of ornamentation is here seen in the highest degree of perfection, some say almost to debasement of style; but I do not agree with this view at all, the very style of the Corinthian almost inviting the profusion of detail.

The outer peristyle was upheld by forty-two plain shafts and a rich entablature, but the inner columns of the pronaos were fluted and exceedingly rich. Looking up, it is observed that the soffit between the columns and the cella wall is composed of huge stones divided into hexagonal panels, each one containing a god or goddess enriched amid a mass of sculpture. Thus were the gods depicted as constantly looking down upon the people and noting their very life.

Look at the huge column on the south side; it has fallen bodily against the cella wall, but not even such a shock has served to break the iron-dowelled bond of the drums. The bases of its mates all around lie exposed; enormous stones lie scattered about, and the whole scene is inspiring in the highest degree from its magnitude and beauty of detail.

The entrance portal must have been most beautiful in its perfect state, for its wide architrave, frieze and cornice was a mass of enrichment, and the supporting brackets are well proportioned. It has always been a question how far enrichment

might be carried without detriment, but it seems to me that given the purity of form and proportion of members, purely classical enrichment adds to rather than detracts from the work. This doorway is the best example of this matter, and is here most satisfactorily answered to my mind. The lintel was in three pieces, but the central voussoir being displaced by an earthquake in 1759, it was found necessary later to build a pier under it, which, however, covered up a most interesting carving on the soffit. A photograph taken before the pier was required shows a spirited eagle with outstretched wings, a caduceus in his talons and a garland in his beak, which is held at the ends by genii. What the significance of this enrichment was, if any, I do not know.

The interior of the temple is choked up with *débris* of cornice and column, but the two divisions are marked by a screen with steps entering the sanctuary beyond. The length is 125 feet and the breadth 68 feet.

The dividing screen must have been very beautiful, for on each side was an enormous slab with figures in alto-rilievo, which told of the sacrificial processions that undoubtedly took place from within its walls. Back of the slabs were massive enriched pillars and from the *débris* it seems to show that an arch sprang from the pillars.

Before entering the sanctuary, however, note that the side walls of the temple were formed by engaged columns of the Corinthian order, between which were niches with pedimented hoods, under which are the bases for statues. Again it is shown how large a place sculpture occupied in the minds of these builders, and one longs to know more in regard to their characters.

Return now to the entrance and people the sanctuary in the rear with the crowning feature of this temple. It could have been no other than the colossal statue of Jupiter, for it was here that the people assembled to consult the oracle and receive the response of the god. As in the Temple of Isis at Pompeii, a secret stair led to the interior of the image, and it was from the lips of the statue that the priests spoke. This passage is still seen. That this fact was known to the people, however, is not at all sure, for the priests acted upon the supposition that the gods spoke through them, and undoubtedly so taught the people. Herodotus remarks that, "These priests assert, though I cannot credit what they say that the god himself comes to the temple and reclines on a bed, in the same manner as the Egyptians say happens at Thebes in Egypt; in the same way, also, the priestess who utters the oracles at Pataræ in Lycia, when the god is there is shut up during the night in the temple with the god."

But at any rate we have only to build up once more in our minds these broken walls, fill the niches with statues, and rear the colossal god in his sanctuary; then approach with the multitude, and we can better understand the enthusiasm of the people, who, resting their faith upon the promises of the gods, saw the incense ascend from the altar, and heard the voice from the sacred shroud of smoke. The decision of fate was accepted, and the destiny of a nation oftentimes hung upon its interpretation.

We leave the temple enclosure, retrace our steps through the passages of the great court, and are soon at the hotel once more. The sun has set, the moon has risen from over the long range of distant mountains, and as we look from the windows once more, the six white sentinel columns stand out from their soft background and rear their heads heavenward.

GLASGOW ARCHITECTURAL ASSOCIATION.

AT a meeting of this Association, held on Tuesday evening in the rooms of the Philosophical Society, 207 Bath Street—Mr. A. N. Paterson, president, in the chair—Mr. S. Herbert Capper, architect, Edinburgh, delivered a lecture on "The Monks and their Abbeys in Olden Days." At the outset Mr. Capper spoke of the difference between the monastic life of the East with its rigid asceticism, and that of the West, where the monks lived together for a common end. When the Benedictines fell away from a strict observance of their early rule, the lecturer pointed out how a reformation towards more primitive austerity was begun at Cîteaux by Robert, of Champagne, and was continued and spread by St. Bernard, of Clairvaux. The Cistercian order, to which St. Bernard belonged, also became popular all over Europe, and was especially so in this country. In the Cistercian monastery the lay brother played an important part, and Mr. Capper explained how his appearance there modified the architectural conditions of the abbey buildings. By the aid of limelight a large number of typical examples of Benedictine and Cistercian, abbeys, and churches were thrown upon the screen and their points of difference explained. Views were likewise shown of cloisters, kitchens, refectories, &c., and of the internal arrangements of the churches and cloistral buildings. There was a crowded audience, who followed the lecture with the greatest interest. On the motion of Mr. Wm. Connes, vice-president, a vote of thanks was cordially given to the lecturer.

Memorial to the Late Rev. John Foy.

SIR,—It is proposed to erect over the grave of the late Rev. John Foy a plain but suitable marble cross, and if possible at least a memorial tablet in the church of St. Thomas of Canterbury, at St. Leonards-on-Sea, of which mission he was for thirty-five years the esteemed rector. To perpetuate this, and also to record his indefatigable labours and kindness of heart, it has been decided by some friends of the late rev. Father, with the approbation of the Rev. Fr. Ottley (the present rector), to appeal for funds to carry out the above proposed memorial. Subscriptions will be received by Mr. J. Klee, Audley House, 17 Church Road, St. Leonards-on-Sea; or to yours obediently
E. BONIFACE.

43 Southwater Road, St. Leonards-on-Sea:
January 21, 1895.

GENERAL.

The Late Earl of Orford has bequeathed a portrait of James Stuart, the Pretender, by Largilliere, to the National Portrait Gallery.

Alderman Bell on Tuesday laid the foundation-stone of the new building for the Commissioners of Sewers. The plans were prepared by the late Colonel Haywood. Messrs. Chessum & Sons are the contractors, their tender being 32,266*l*.

M. Natalis Rondot, of Lyons, has been elected a corresponding member of the Académie des Beaux-Arts, in succession to the late Sir Charles Newton.

Mr. Walter Gay, the American painter, has been nominated a Chevalier of the Legion of Honour.

A Design by Mr. W. L. Carruthers, architect, has been selected for the new church in the Barnhill district of Inverness. The church will accommodate 400, and will cost about 2,000*l*.

Subscriptions amounting to 300*l*., from a number of Scotch Presbyterians in Australia, have been sent to the Rev. Dr. Cameron Lees towards placing a memorial to John Knox in St. Giles's Cathedral, Edinburgh.

Dr. F. J. Waldo, medical officer of health of St. George's, Southwark, and of the Inner and Middle Temple, has been appointed tutor in public health to St. Bartholomew's.

The Dublin Arts Club Exhibition was formally opened on Monday afternoon by the Lord-Lieutenant.

Mr. A. Marshall M'Kenzie, A.R.S.A., has designed a pulpit for the new Crathie Church. It is being erected in different kinds of Scotch granite, and Princess Louise has sent a collection of Scottish pebbles and marbles for the ornamentation of the pulpit, collected by her on the island of Iona.

The Cambrian Archæological Society have been invited to hold their next annual gathering in Cornwall.

Mr. T. W. Baker, of Oakfield House, Balsall Heath, has been appointed architect for the proposed extension of the Warwickshire County cricket pavilion.

Lord Mount-Edgcumbe, as Lord-Lieutenant of Cornwall, will on Monday, February 4, present the testimonial to Mr. Silvanus Trevail, mayor of Truro, for which subscriptions have been given in recognition of important public services.

The Society of Cardiff Architects meet at 3 P.M. this afternoon for the purpose of considering the desirability of drawing up a memorial to be presented to the Corporation, with a view to asking that body to have an open competition among the architects of the county borough of Cardiff for the proposed new museum and art gallery in Park Place.

Mr. A. M'Gibbon, architect, on Tuesday delivered a lecture in the Glasgow Corporation Art Galleries on "The Design and Arrangement of the Mediæval Church."

Messrs. Baker & Sons have sold by auction ground-rents amounting to 400*l*. per annum secured on ninety-eight small houses and shops at Peckham, Camberwell, Dulwich and Clapham, which realised 12,000*l*., being an average of thirty years' purchase.

Mr. Charles Bartholomew, C.E., died at his residence at Ealing on the 12th inst. in his eighty-ninth year. In early life he was engaged in constructing a portion of the Aire and Calder Navigation. Subsequently he was employed in railway work and became engineer in chief of the River Don Navigation and South Yorkshire Railway, of which combined enterprises he was subsequently a director. He also took part in opening up the coalfield of South Yorkshire, and to the time of his death actively participated in the management of the collieries with which he was connected.

The Architect.

THE WEEK.

THE last circular issued by the Science and Art Department may instigate a reform in the science schools, for what is proposed is a stoppage of the cramming which has made the schools, or rather, the teachers and students, ridiculous. Every year examiners like Professor HUXLEY have protested against the system, but in vain. As long as payment on results prevailed there could not be a change. In theory the principle appeared satisfactory to the British mind, but when manipulated as it was by officers of all grades, it merely aided in producing a mockery of science. It is now proposed that payment by results is to come to an end in May, and will be superseded by payment on inspection. There are now competent inspectors, and Mr. ACLAND considers that with their aid he can make the change. The rule will apply to about 120 science schools. It remains to be seen whether the new system can be loyally carried out. It may not at first bring any increased emoluments to the teachers, and the compilers of the departmental returns will not be able to expatiate about the amazing increase in the number of trained students in science which are turned out in the classes. But if instead of a sham success there is a little genuine knowledge extended among the people, the country will not be a loser.

A SPECIAL meeting of the Cardiff, South Wales and Monmouthshire Architects' Society was held on Friday afternoon in Cardiff, for the purpose of considering the question of throwing open to competition the plans for the new museum and art gallery. It was unanimously resolved that the following memorial be sent to the Cardiff museum committee:—"That the Cardiff, South Wales and Monmouthshire Architects' Society memorialise the Cardiff museum committee to the following effect:—That unless they have already pledged themselves to any architect, they should invite a public competition for designs for the new museum buildings proposed to be erected in Park Place, the competition to be under the rules of the Royal Institute of British Architects." It was stated that Mr. EDWIN SEWARD, a member of the Society, claimed to have been already retained as architect by the museum committee.

THE following declaration of the status of an architect was adopted at a meeting of the Royal Institute of Architects of Ireland on Saturday:—(1) The present well-defined legal relation of the architect to the employer is that of servant, agent and adviser; and to the builder of arbiter between him and the employer. The position of the architect confers on him no claim to dictate as to his employer's expenditure, nor as to the materials, workmanship, or manufactured goods he elects to spend his money on. The architect's privileges are limited to persuasion and protest against anything injudicious which might be credited to the architect by the general public. An architect, in his fiduciary capacity, who, for any private motive whatever, permits materials or workmanship or goods of any kind to be charged against his employer, without his special consent, at a higher cost than the like could have been obtained for elsewhere in open market, commits a grave breach of trust. (2) The relations of the architect to the contractor are limited to insistence on good and sound work, and that all goods supplied are up to contract standard, and that the contractor is justly paid, and the work finished up to time. It is not open to the architect to concern himself with the economic management of the contractor's business, on the profits of which he lives, nor to control his purchases or relations between him and his men. The discussion by architects with outside persons on such matters as lie within the liberty of action of employer or contractor is an impropriety. (3) The foundation principle of this Institute is the advancement of architecture in Ireland. While it is daily more incumbent on every Irish architect, in view of the extraordinary development of architecture and building resources, to acquaint himself by travel and diligent study with newest inventions,

construction and materials, so as to keep architecture in Ireland abreast of its progress in other countries, the unanimous preference of Irish architects is for workmen and products of Ireland, and to employ them within their rights, limited as before defined. It should further be the policy of Irish architects to introduce to Ireland all newest ideas of construction, building appliances and materials, and make them known, and to encourage the development of native product of all such novelties or improvements, with superiority if possible. It is desirable that the Institute should resume its functions, somewhat neglected, of professional discussion, &c., of all economic questions affecting the progress of architecture, and that it should invite from master builders, tradesmen, manufacturers and others interested in architecture, communications in writing on debatable questions which have not a personal tendency; and that the deliberate opinion of the body of architects on controverted subjects should be published in the Press.

THE new building of the Royal United Service Institution, which adjoins INIGO JONES's banqueting-hall, is now ready for opening. The building is constructed of brick, Portland stone and granite, and is fireproof both in roof and floors. The principal or western front is towards Whitehall, but it has also an elevation facing Whitehall Gardens, on which the lecture theatre abuts. The heavy exhibits are housed in the crypt, while the arms, armour and models are arranged in the upper hall. The staircases are adorned by trophies of arms. At the levels of the lower gallery of the hall and of the upper galleries sliding doors of communication connect the old building with the new one, which comprises, on the first floor, an entrance-hall, porter's-room, service stair and passenger lift to the principal floors, clerks' office and lavatories for members, staircase hall, a large lecture theatre capable of seating nearly 400, and a lecturer's-room. The theatre has a separate exit towards Whitehall Gardens. On the main floor, at the level of the banqueting-hall, there are, facing Whitehall, a council-room and secretary's room with loggia, overlooking the theatre. On the first floor there is a large newspaper-room, running the whole length of the Whitehall front, and reference library over the theatre, with accommodation for about 30,000 books, and librarian's room adjoining. On the second floor, at the level of the banqueting-hall gallery, there is a large waiting-room over the newspaper-room, and the staircase hall on this floor opens into the gallery of the reference library. On the top floor is a large topographical room and also caretaker's quarters. In the basement is the boiler-room, from which the building is warmed with hot water, and storage cellars of various kinds. The architects are Messrs. ASTON WEBB & E. INGRESS BELL. It is estimated that the cost of the new buildings and of preparing the banqueting-hall and crypt for the museum will be about 25,000/.

A MEETING of the consultative council of the Building Trades Exhibition was held at the offices of the exhibition, 222 Strand, W.C., on Wednesday, the 30th ult., Professor BANISTER FLETCHER in the chair. There were also present Messrs. E. W. MOUNTFORD, T. LOCKE-WORTHINGTON, H. H. COLLINS, GILBERT WOOD, H. GREVILLE MONTGOMERY, G. M. CALLENDER and T. FREEMAN, hon. sec. It was resolved that popular lectures should be given by architects and others as last year, upon subjects of interest to the manufacturer, and that the competitions in handicraft by workmen in all branches of the trade should be continued and still further developed. It was suggested that various experiments in the crushing strain of materials should take place, and that the Council should take upon themselves to make tests of such materials as exhibitors should care to submit to them. The affairs of the exhibition were stated to be in a very flourishing condition, the number and variety of exhibitors already far exceeding those of many years past.

FEW men were more closely associated with archæology in Lancashire than Mr. JOHN PARSONS EARWAKER, who died on Wednesday. He was born in Manchester in 1847. His most important work was the superintending of the reproduction of the records of the Court Leet of Manchester, which was entrusted to him by the Corporation.

DOMESDAY BOOK AND HOUSES.

A GREAT change has taken place in the manner of judging the famous Survey or inventory which was ordered by WILLIAM THE CONQUEROR. It is no longer supposed to have been an inquisitionary document which would enable the strangers to exact an undue share of the property of the natives. The Survey was inspired by a desire to insure the equitable taxation of Englishmen as well as to bring in such a revenue to WILLIAM as would be beyond the dreams of avarice. The account which LINGARD gives of the origin of the Survey, although very brief, is sufficiently correct to be quoted:—

It could not be supposed that the Normans in the provinces, foreigners as they were, and indebted for their possessions to the sword, would respect customs which they deemed barbarous, when they thought them prejudicial to their interests. But while they tyrannised over the natives, they often defrauded the Crown of its ancient rights, and the king, treading perhaps in the footsteps of the great Alfred, to put an end to all uncertainty ordered an exact survey to be made of every hide of land in the kingdom. Commissioners were sent into the counties, with authority to empanel a jury in each hundred, from whose presentments and verdicts the necessary information might be obtained. They directed their inquiries to every interesting particular, the extent of each estate, its division into arable land, pasture, meadow and wood, the names of the owner, tenants and sub-tenants, the number of the inhabitants and their condition, whether it was free or servile; the nature and the obligations of the tenure, the estimated value before and since the Conquest, and the amount of the land tax paid at each of these periods. The returns were transmitted to a board sitting at Winchester, by which they were arranged in order and placed upon record.

It was the policy of WILLIAM to make as few changes as possible in the Saxon laws, and in the survey for Domesday a similar respect was shown for ancient arrangements. There are in it no novel divisions of England or of its inhabitants. Shires (which were not always counties) and boroughs, hundreds, tythings or decennaries, wapentakes and wards are employed just as they were in the time of EDWARD THE CONFESSOR. The feudal distinctions between freemen, foreigners, strangers and villeins are recognised. The tenures are mentioned and the obligations they imposed. Domesday Book is, therefore, not a memorial of Norman innovations, but a record of what had survived after many centuries of regular government, and which helped to distinguish England from the rest of the world.

The Survey was accordingly of much more importance in the eleventh century than a general collection of the poor law union assessments, which are the nearest approach to it, would be in our time. The two volumes suggested to WILLIAM and his councillors what guarantees existed for the preservation of order. We should remember that in Saxon England an effective, if primitive, method was adopted which enabled the rulers to dispense with a police force. The reeve, sheriff or præpositus was an influential officer in preserving the public peace, but the main part of his business was to see that every man within his jurisdiction was, as it were, bound over not only to keep the peace himself, but was part surety for the keeping of it by his neighbours. A foreigner could not enter the country unless one or more freemen became responsible for him. A man could not leave his own shire or lordship without authority. That restriction was relaxed in course of time, but that it prevailed when the Survey was in progress is shown by the occasional entry, "he may go where he will," as an indication of the possession of a privilege which was worth attention.

The great ALFRED, when he ordered the Survey to which DR. LINGARD refers, divided England into counties, hundreds and tythings. A tything or tenth was the origin of our word town, for, says FINCH, "A town is a precinct anciently containing ten families, whereupon in some countries they are called 'tythings,' within one of which tythings every man must be dwelling, and find sureties for his good behaviour, else he that taketh him into his house is to be accused on the Leet." HENRY, following what is said by WILKINS in the "*Leges Saxonice*," affirms also that "All the members of each decennary were mutual pledges for each other's obedience to the laws, and answerable with some equitable restrictions for their disobedience. Whoever was not a member of some decennary was considered as a vagabond who could claim no protection or benefit from the laws of the country." Domesday accord-

ingly enabled the authorities to realise to what extent the tythings or towns were an obstacle to the increase of the "Vagrant Lackalls" which continue to be one of the miseries of England. The tythings were no less serviceable to the Normans in preventing the hatching of conspiracies. The Survey enabled the invaders to estimate the strength and weakness of their position, and that so great an undertaking was accomplished in the short space of four years testifies, as CARLYLE says, what kind of under-secretaries and officials WILLIAM appointed — "silent officials and secretaries, not wasting themselves on parliamentary talk; reserving all their intelligence for the silent survey of the huge dumb fact, silent consideration how they might compass the mastery of that."

To consider the references to the houses throughout the Survey would be a stupendous task: we must limit ourselves to a few of those which are found in the returns from the boroughs. In the first place, it is to be regretted that the system of classification which must have been prepared for the use of the surveyors is unknown. It is impossible to say how the collection of low, irregular buildings, court-yards and enclosures of CEDRIC the Saxon, of which we read in "*Ivanhoe*," would be described. There are entries in Domesday which must puzzle a modern valuer or assessor. We find, for instance, that in Nottingham ROGER DE BUSLI paid 4s. 7d. on account of three mansions, which contained eleven houses. Were the latter chambers? In the same town RADULPH, the son of HUBERT, is said to have eleven houses, in which three merchants dwell. It might be concluded that the three merchants were tenants or sub-tenants for the eleven, but it is not improbable, according to modern notions, that they occupied no more than three shops, and that the remainder of the property was let to knights. For in the same folio we read of WILLIAM PEVREL having twelve houses of knights and forty-eight of merchants, while RALF DE BURUN held thirteen houses of knights, and in one of them a merchant lived. In all ages merchants were important agents in upholding society, and at a later time they became the most influential of the inhabitants of towns. But the especial way in which they are designated in Domesday suggests that they were assumed to be either foreigners or pedlars, and therefore it was well to keep a watch on them. Whatever was the cause they do not appear to be included among the burgesses. We also find distinctions between houses and halls. Thus, in Lincoln, the hall of one individual is free from all customs or dues, whereas another, it is noted, has a house without a hall and pays dues. In that city a burgess possessed the privilege of selling his house and removing elsewhere. But the disposal of interest in property and especially land was no easy undertaking. Small proprietors were puzzles to the officials. It is recorded with amazement that in the vill of Bideham, in Bedford, one GODWIN held half a hide of land which "he was able to give to whom he willed." Another burgess, named ORDU, could dispose of half a hide and the fourth part of a yardland, and ULMARUS could give two parts of a yardland. Bedford evidently was undisciplined, and must have given trouble to the surveyors.

As the people were held to be responsible for the good conduct of their neighbours, they were also compelled to be no less careful in looking after houses. Every building was of importance in the eyes of the State, and it was unlucky for those who allowed fire to approach one. In the survey of Shrewsbury it is stated that if the house of a burgess should be burnt by any accident or event, although there was no negligence, he was to forfeit forty shillings to the king and two shillings to each of the adjoining neighbours. It was accordingly the interest of every burgess to aid in preventing fires from spreading, for a few sparks might ignite other houses, and the tenants were fined in addition to their losses. In Chester, the rule was that the man who owned the house in which the fire commenced should pay three ores of money and three shillings to his nearest neighbours.

The king's highway had, in those days, a signification which we cannot understand. Interference with it was a serious offence. We can imagine it brought about much inconvenience to a culprit, for it is recorded among the customs of Canterbury that if a man were to dig a

trench or set up a paling without authority, the king's reeve was to pursue him whithersoever he fled, and obtain from him satisfaction for the king. It was probably owing to the stringency of the regulations concerning public ways in boroughs that so many of the inhabitants were induced to set up their residences in the ditch near the walls. A lawsuit in the time of EDWARD I. is evidence that several were then existing in the Canterbury ditch, but it was not unhealthy, for it was said to be 150 feet in width. There were also houses in the ditches at York and Nottingham. It is possible the houses belonged to people who were connected in some way with the defence or reparation of the walls or ramparts. The Survey records that in Oxford the king possessed twenty mural mansions, which were free from all dues except work on the wall. It is stated that if the holder of the house neglected the work, he must either pay a fine of forty shillings to the king or forfeit his house.

There were various other obligations. In Hereford a tenant was to pay $7\frac{1}{2}d.$ and $4d.$ towards hire of horses, to give four days' help in mowing and one day in gathering the hay, if the sheriff ordered. If he possessed a horse he was to accompany the sheriff three times a year, and whenever the king went a-hunting a man from every house was to stand in the wood. Six smiths were allowed in the city; each paid a penny rent for his forge. Each was to make 120 nails from iron supplied, for which they received three-pence. The seven moneyers of Hereford (one was an episcopal officer) gave each eighteen shillings for the coinage die, and twenty shillings a month for the privilege. They were obliged to coin as much money as the king required when he came to Hereford, and they followed the sheriff in expeditions to Wales. If any of them was afraid to go, he was fined forty shillings. Many other customs prevailed by which services were accepted in lieu of rent.

There is a statement of INGULF that ORDERIC confirms, which shows that WILLIAM's commissioners were often deceived. We cannot credit that the number of houses given as waste or unprofitable was correct. The coming of the Normans could not have given an extraordinary impulse to speculative building, yet in almost every town many houses are returned as useless. In York there are 50 inhabited mansions, 400 uninhabited, and 540 from which no money can be derived. There were also broken-down burgesses, or "burgensēs minores," who generally escaped with the moderate tax of a penny a year. In spite of all the deductions and evasions, WILLIAM could not complain of his incomings. If his ambition was to become the wealthiest of European monarchs, he succeeded. It was calculated by one of his contemporaries that his revenue amounted to 1,061*l.* 10*s.* 1*½d.* per day, and the equivalent of that sum in current coin appears so incredible, there is always some hesitation in announcing it.

The money question is undoubtedly of primary importance in Domesday Book, and is continually asserting itself. For example, the phrase "a guildhall of burgesses" very often occurs in the folios. Imagination need not picture those places as picturesque buildings in which stout burghers debated. They were only the offices where the tax collectors were to be found. "Guildan" then meant paying, not a guild, a municipal corporation or a body of craftsmen or devotees; and WILLIAM and his officials were eager to be assured that no inhabitant could plead ignorance of the place where he was to pay all his dues to the State, which, in most instances, included rent, or be able to complain of having to trudge a long distance to reach the collector.

There was no part of England from whence WILLIAM was likely to derive more money than from London. Yet in the whole of Domesday there is no return relating to it. Sir HENRY ELLIS suggested that the reason of the omission was that, prior to the Survey, London was graced with peculiar and extensive privileges, and if so it could not come under the same sort of classification as other towns. Winchester also was excluded, but it is known there was a separate Domesday for that city called the "Book of Winton." There may have been also a London Domesday which no longer exists. The absence of the record deprives us of information concerning the houses which were the most interesting in the country.

THE BRIDGEWATER GALLERY.

IT may be assumed that when a winter exhibition of works by old masters is opened, the first question with many amateurs is whether any pictures from Bridgewater House have been secured? It seems unaccountable that year after year one of the very few great collections in London should be kept intact, in spite of all the entreaties of the Academicians, and one, too, which is so close to Burlington House as to remove any apprehension about the safety of pictures while on the way to an exhibition. The great obstacle to the appearance of any of the examples on the walls of the Academy is a clause in one of the deeds which prohibits the removal of any of the pictures from the galleries for even a brief period. It is true that in 1857 there was apparently a departure from the prescribed rule, for about half a dozen of the pictures were exhibited at Manchester, but we suppose the exceptional liberality arose out of the intimate connection of the BRIDGEWATER family with Lancashire, and, moreover, the pictures in question, which were not the most valuable in the collection, may have been acquired under circumstances which would allow them to be gazed on by the public without diminution of their interest.

The most valuable part of the Bridgewater collection was acquired on terms the recollection of which must always excite envy in the minds of amateurs. The pictures we refer to belonged to the Orleans or Palais Royal collection. They had become the property of PHILIPPE D'EGALITÉ. To serve his own interests, he was stirring up disaffection in France, and under the guise of patriotism was plotting against LOUIS XVI. Money was needed for his agents, and, as he was indifferent to art, it was no sacrifice to sell the pictures he had inherited. They were gathered by the Duke of ORLEANS, who was Regent of France during the minority of LOUIS XV. For twenty years he employed agents throughout Europe to acquire masterpieces for him. In that way he was able to secure the pictures which belonged to CHRISTINA of Sweden, the Cardinals RICHELIEU and MAZARIN, the Duc de GRAMMONT and others, amounting altogether to 485 works. The majority were paintings by Italian masters, and VOLTAIRE refers to the Regent's collection as being one of the causes which gave a tendency to French taste. Some of the pictures were displeasing to the Regent's son, or rather to the moralists who surrounded him, and were ordered to be destroyed, but with all deductions the collection, when it passed into the possession of PHILIPPE D'EGALITÉ, was worthy of any king's gallery. Owing to the need to obtain money the pictures were sacrificed. The German, Flemish and Dutch examples were sold to THOMAS MOORE SLADE, representing an English syndicate, for 350,000 francs; a banker from Brussels secured the Italian and French pictures for 750,000 francs, but becoming apprehensive resold them for 900,000 francs to LABORDE DE MEREVILLE, who wisely despatched them to London. BRYAN, the author of the "Dictionary of Painters," saw them, and persuaded the Duke of BRIDGEWATER to invest 42,000*l.* in purchasing the three hundred and five paintings. Afterwards BRYAN made a valuation in detail, which worked out to 72,000*l.* The Duke retained ninety-four. He allowed his nephew (afterwards Marquis of STAFFORD) to purchase one-fourth of the selected number, and conferred a similar favour on Lord CARLISLE. The duke's share of forty-seven pictures, at BRYAN's prices, would cost him 42,313*l.* The two quarter shares amounted to 21,300*l.* The remaining pictures were offered for sale at an exhibition which was held in the Lyceum in the Strand. On the first day Mr. ANGERSTEIN gave 3,500 guineas for the *Raising of Lazarus*, which is now in the National Gallery. During the time the exhibition was open pictures to the value of 33,544*l.* were sold. The sums paid for admission amounted to 7,500*l.* The surplus works were sold by auction and realised 4,273*l.* It will thus be seen that after reserving ninety-four works which were the most valuable, a sum of 45,317*l.* was derived out of the remainder. In other words, the duke and his two privileged friends were enabled to obtain the pictures most admired by them without any expense. It is commonly said they paid about 2,000 guineas for their good fortune, but the supposition is only a concession to the commercial spirit of the country, which prefers a debit and credit to a one-sided account.

The forty-seven pictures from the Orleans galleries were added to those possessed by the Duke of BRIDGEWATER, and a great many others were afterwards purchased. The collection is therefore considered by some authorities to be the most valuable in England. But the market value of paintings, and especially those belonging to the Italian school, is so uncertain, it is difficult to say what price would be obtained for the pictures if, let us suppose, they were brought into the market in order to obtain money to advance the prosperity of the Manchester Canal. Four pictures by RAPHAEL, five by TITIAN, with the examples by CLAUDE, REMBRANDT, CUYP, TENIERS, BERGHEM, if those by the CARACCI, N. POUSSIN and GUIDO were out of favour, would attract competitors from all parts of the world.

There is, however, degradation for it when the worth of a picture is determined by a dealer's standard. The majority of the pieces in Bridgewater House are to be prized for other reasons. The large *St. Gregory attended by Angels*, which was painted for the Monastery of San Gregorio in Rome by ANNIBALE CARACCI, has an interest for all who find a pleasure in smuggling. It was among the spoils which were destined for the Louvre, but somehow an Englishman and an Italian became joint proprietors of the altar-piece. It was concealed in the cellar of a house. A rule was made that every painting which was to be sent from Rome should be scrutinised in the presence of a cardinal, and stamped by him. To evade the rule a scheme was arranged. An artist was obtained to paint a distemper copy of GUIDO'S *St. Michael* over CARACCI'S work. Then an Englishman was discovered to whose lodgings the dual painting was sent. He represented to the cardinal that he had purchased a copy of the *St. Michael*, but as it could not be easily removed he would be grateful if the examination could be gone through at his lodging. The cardinal was willing to oblige all Englishmen, and agreed to the proposal. He imagined he was dealing with a gentleman. By that dodge the picture was allowed to be taken from Rome. It reached England in 1801, and found its way to a place among the Duke of BRIDGEWATER'S Italian works. The annals of most collections are full of similar stories, but whether they are creditable to the men who were the actors is another question.

It is not the only picture with a history. The *Cupid* by PARMIGIANO was originally painted for the Chevalier BAYARD. RAPHAEL'S circular *La Vierge au Palmier*, one of his earlier works, was inherited by two sisters, who preferred to break the panel in two and each to possess a fragment rather than agree to possess it by turns. The picture must have been injured in the operation, for the late Sir A. H. LAYARD considered that the figure of St. JOSEPH was the work of an inferior hand or was entirely painted over. The *Madonna del Passeggio* was presented to PHILIP II. of Spain by the Duke of URBINO. It found its way to Prague, from whence it was carried off to Sweden by GUSTAVUS ADOLPHUS. Queen CHRISTINA bequeathed it to one of her favourites, who sold it to an Italian prince. Next it passed to the Duke of ORLEANS, and eventually to Cleveland Row. POUSSIN'S series illustrating the seven sacraments was purchased by the Duke of ORLEANS for 120,000 francs. BRYAN'S valuation of them was 4,900! REYNOLDS considered them to be typical of POUSSIN'S later manner, which was much softer and richer than his earlier and drier style, and as showing more union between the figures and the ground.

The examples by TITIAN justify VASARI'S epithets, *Judicioso, bello, e stupendo!* The *Diana and Calisto* and *Diana and Actæon* were completed in the master's eighty-second year, and are marvellous in the skill with which figures and background are combined in colour effects. At one time it was supposed the two were painted for HENRY VIII., and that they belonged to CHARLES I. HAZLITT says that in them, "tone, not form, predominates; there is not a distinct line in the pictures, but a gusto, a rich taste of colours is left upon the eye, as if it were the palate." The *Venus à la Coquille* is not a goddess according to the Greek type, but what is seen of the form is beautiful, and the sea in which she stands is of a blue which is only visible in the south. The *Four Ages*, like the *Sacred and Profane Love*, is one of TITIAN'S enigmas which are as obscure as any of DÜRER'S. GUIDO'S *Assumption* is one of

his great works, and ROMANO'S *Infancy of Hercules* is superior to any example of the master in England.

It is a pity that so many noble examples of the Italian school are not to be seen and studied, if it were only by instalments. The Flemish and Dutch pictures are also valuable. If artists, students and amateurs were enabled to realise the importance of the BRIDGEWATER collection, and were to urge the advantages which would arise if the pictures were allowed to become as visible as those in other private galleries, their desires might be granted. English law courts are powerful, and of late years a rational interpretation has been taken of many deeds which, when considered literally, were exacting in their precautions. If the documents which create a trust in the pictures in Bridgewater House were examined in the modern judicial spirit, they also might be found to be serviceable to the community.

THE STUDY OF MÆDIEVAL DOMESTIC ARCHITECTURE.*

THE most neglected phase of Mediæval archæology is that which relates to the dwelling. Architectural histories are scarcely better, down to the time of the Renaissance, than histories of religious architecture. With the Renaissance, the dwelling-house in its many forms assumed so important an aspect that it has been absolutely necessary for our historians to give some attention to it. But for the time previous to the Renaissance little has been done. Of English books there is almost less than nothing in the way of literature. Fergusson, who, notwithstanding his many obvious faults, has produced the most considerable history of architecture in England, refers to the quantity of ancient domestic architecture, especially that in France, but makes no use of it. Von Reber, in his admirable handbooks, scarcely does more than mention domestic architecture by name, while Mr. Moore, an American writer, does not refer to this phase of architecture at all in his work so broadly titled "Character and Development of Gothic Architecture." Certain phases of ancient domestic architecture in England have been well studied and published, and there is, perhaps, little to be done in that country, save in the direction of publishing further detail.

But it is not altogether correct to say that nothing has been done; a good deal has been accomplished, and is being accomplished, which is important to remember, but as yet there has been no general survey of the whole field of domestic architecture from the earliest times down to the end of the last century. My object in the present note—for it is much too fragmentary to deserve the name of paper—is simply to direct attention to this somewhat neglected phase of architectural history and to suggest one or two plans for work in it.

Personally, I have no actual acquaintance with ancient domestic architecture outside France, and I am therefore chiefly concerned with that country. Last summer I visited many out of the way places in France, and was quite unprepared for the enormous number of houses of all sorts that I met with in my wanderings. Not all of these were of historical value; many of them were without special artistic or picturesque value, though their general effect, when seen up narrow streets or in small bits, was intensely picturesque; a good deal has been injured by restorations, by rebuildings and by repairs, until sometimes only a window-frame or a huge column remains to tell or to suggest what the original structure was like. By far the larger part of these ancient buildings are unstudied and unknown. Even the photographic series of the Commission of Historical Monuments contain but a few of them.

For example, the new catalogue of M. Robert, the official photographer to the Commission, which has just been published, contains but seven photographs of the old buildings of the town of Montferrand, and two of these are details of whole structures included in the other photographs. This town of Montferrand, which is not inaccessible at all, being reached in a few minutes by electric railway from Clermont, is full of old houses, scarcely any buildings of importance having been erected there since the sixteenth century. I do not wish to hint that all its structures are of great interest; many of them are not, but several are very important, with interesting courts, and which well deserve attentive study. Of Sarlat, which is one of the most picturesque and strange towns in France, in some respects the most striking place I have seen, M. Robert offers but four photographs, though I am sure he could have gathered forty easier than the trouble it must have been to have picked out the four. Of Mirepoix, M. Robert has but one photograph, and while that, fortunately enough, is the most striking and interesting house in the town, there are many others interesting, perhaps more singular than interesting,

* A paper read before the Archaeological Institute of America by Mr. Berr Ferree.

and the great square of the city is certainly one of the most remarkable in Europe. And I might take up fifty towns and make the same report on them; scarcely a village in France that does not contain some type of ancient house architecture of more or less interest. And while speaking of the subject of photographs, it may be well to mention that almost nothing is done by local photographers. In some few localities where there are well-known curiosities that are visited by occasional tourists, small photographs can be had of scarce more value than the simplest souvenirs. Anything like adequate photographing by local photographers is quite unknown.

It is entirely natural that France, and, indeed, all the less visited and therefore less changed parts of the Continent, should abound in examples of ancient domestic architecture. For a single church there would be, and is, a hundred or more houses. So far as volume goes, there is no comparison between ecclesiastical and domestic architecture, though the quality is necessarily different. Houses, as works of art, do not approach churches in this respect, and in those attempted histories of architecture in which the study of form is made the dominant question, it is perhaps natural that the more ornamental structures should receive more attention than the more useful though the less ornate. Still, though the reason for this difference in treatment is apparent enough, there is no reason why, in this enlightened epoch, when everything that throws light on the development of human culture is eagerly studied and investigated, we should continue to close our eyes to the quantity of domestic architecture that has come down from previous times.

Obviously the circumstance that many of these dwellings have been repaired almost beyond recognition, that many of them are still inhabited, that many of them have lost their real artistic interest, has had much to do with the neglect with which they have been treated. The traveller who goes among them needs no imagination to reproduce the life of the Middle Ages, save the costume of the people. Climb the hill of Le Puy to its strange cathedral, and in its vertical streets one can almost smell the thirteenth century. Walk along the streets of Tulle and of Sarlat, and you can feel the intense cold dampness oozing out of the houses as it has oozed for hundreds of years. Go into Sisteron and see the narrow, ugly alleys, arched over until, in broad daylight, one has almost to feel one's way, and you will realise what life in the Middle Ages must have been so far as the dwelling-house was concerned.

But I am not arguing for a revivification of the Middle Ages; all I wish to do is to point out this neglected phase of archaeological study and to hint at its exceeding richness. I have already referred to the relatively slight attempts to perpetuate this work in the photographs of the Commission of Historical Monuments. What has been done otherwise?

In some respects, a good deal. That is to say, French archaeological literature contains a good number of monographs on Mediaeval houses of one form or another. But these are mostly important houses. Now this is not what I suggest studying at all, but the unimportant ones, and I am sure the student who ventures into this field will have rich returns for his labours. But these monographs are scattered through the many publications of the French archaeological societies, which we in America scarcely see at all and which even in France are not well circulated. And, furthermore, these studies are undertaken without any special reference to system, to locality, to bearing upon other studies, or even to the history of domestic architecture as a whole. The great desideratum is systematic study on an extended scale.

My chief suggestion is briefly this. Nearly all the more important cities of the French Departments have an archaeological society, whose special purpose is the study of the archaeology of its immediate vicinity. Now, if these societies were to divide up France into a series of districts for the study of its domestic architecture, if each would take its own neighbourhood, and institute or encourage extended study of its domestic monuments, it would be possible, with systematic and organised work, to accomplish a vast deal in a few years, even though each society only took up a few buildings at a time. Most of these organisations publish bulletins or memoirs, and it would add no greater cost to their expenditures to publish reports on these buildings, and thus make common property to the whole world of a rich field of study whose value they as yet scarcely know themselves. Such work should include, first of all, photographing the building in every important aspect, or in any aspect which could, in any way, be considered important or useful. Even if these photographs were never published, the fact that somewhere they could be found, and that negatives were in existence, would be something of value. Important dwellings should be measured and be carefully drawn to scale; and all, important or not, should have their plans drawn. Wherever possible, life histories should be collected—that is to say, repairs, alterations and changes noted, and an actual record made of their present condition. Photographs, drawings and notes must be ample and complete for work in this neglected field to be valuable or worth undertaking.

I suggested at the outset the making of these studies down to the close of the last century. Archaeologists who are more familiar with events prior to the birth of Christ than with those that transpired after it may think this too wide a limit for archaeological study. But archaeological study should not be incomplete if there are later works to supplement it, and the archaeologist who will devote his time to the study of the house may well be asked and expected to continue his research down to the latest times. The architecture of the seventeenth and eighteenth centuries, even in the ecclesiastical form, is scarcely studied; how much more important is it therefore that we try to make the most of its houses. Here again France is very rich, two cities, Toulouse and Bordeaux, and especially the former, being exceedingly rich in monuments of these dates. No one studies these; their forms, their relations to previous dwellings, their influence upon the form of our own dwellings is scarcely known. The architectural type is not beautiful, and in many instances scarcely pleasing; I would rather call it interesting, as every sort of structure must be that illustrates any phase of human culture.

While speaking of Toulouse, I may be permitted to refer to a work recently published in that city that illustrates, in one aspect, the sort of work we need to see applied to every town in Europe. In "L'Album des Monuments et de l'Art ancien du Midi," of which the first part was brought out by the Société Archéologique du Midi de la France, of Toulouse, in 1894, there was printed an archaeological map of the city, in which the houses of different dates were carefully marked, so that the student can, at a glance, tell exactly what buildings of each century are in Toulouse and where they are situated. It is needless to point out the utility of a work such as this. A series of such maps for the chief cities of the Continent would be of the greatest value and interest.

I have no doubt but that those familiar with the architecture of Europe outside of France will agree with me that much the condition I have outlined for that country is true of the balance of the Continent. These conditions, to repeat what I have before stated, are:—(1) an enormously rich field, which (2) has scarcely been worked; (3) many important individual monuments have been studied, especially those of the Renaissance period; (4) what work has been done has been diffuse and without system; (5) a necessity for extended systematic study.

How far work of the nature I have suggested can be carried out by American students I am not prepared to say. It cannot be hastily done, and to be properly performed must entail more or less drudgery. American architectural students may almost be counted out of the race, though their assistance should be welcomed and valued. Earnest as many of these young men are, they want something striking to show for their work; it is the beautiful and the picturesque they are in search of. I doubt if much can be expected from them through the uninteresting nature of much of the material to be studied. It is, further, work that requires long-continued labour to bring adequate returns. A study of a single building is scarcely likely to have the value that the study of a group in the same vicinity would have. It is therefore hardly possible, as the archaeological outlook now is, to hope for much in this department from any but the French themselves. Whether it is in good form to suggest to them that this work needs to be done, whether it is advisable to advocate the general study of European domestic buildings throughout the whole Continent, I must leave to others to determine. My present purpose will have been accomplished when I repeat that in this one subject is an archaeological field, close at hand and ready of access, of most amazing richness. And further, that each day detracts from its volume; each day sees new repairs, new restorations, new changes by people who have no thought of art or of archaeological value. The longer this work is postponed the less there will be for the future historian of this architecture to concern himself with. It would be easy for me to say I know no more important division in archaeological work than this, because I am not familiar with any phase of archaeology save that which relates to the Middle Ages. But I trust the importance of this work, yet to be done, will be recognised, and I earnestly hope the day is not far off when the beginnings will be made. Meanwhile, it would be well for some enterprising person to find out what has already been done. A bibliography on the subject would be enormously helpful, and would have the twofold value of preventing the duplication of work already done, and of showing by contrast how little has been done.

One word on the general method of study. Architecture is not, to my mind, a bare recital of forms; architecture is the result of the efforts of the human mind to provide shelter for the human body, primarily; and, secondarily, to make these shelters as beautiful as possible. The study of domestic architecture is, therefore, a study of human life. Properly undertaken it brings out the meaning and reality of architecture in a way impossible when it is a mass of descriptions only. Two advantages follow from this. The subject is given a real and live interest it could not otherwise have; and, secondly, it puts

architecture before the general public in a living way, before people who now look upon it as the dullest and stupidest of subjects. I am not sure but that this last aspect of the question is the more important; at least, it suggests possibilities from the study of old, and in many cases broken-down houses in Europe that may not be apparent at first thought.

OLD V. NEW LONDON BUILDING ACT.

ON Monday the first important case under the new Building Act was heard at Bow Street before Sir John Bridge, and it revealed a serious flaw in one of the sections. Mr. C. F. Hayward, district surveyor for the parish of St. George, Bloomsbury, was summoned by the building owners of Bedford Court Mansions, who set forth in their information that the defendant had served them with notice of objection to the proposed erection of a certain building, and they called upon him to show why the decision should not be reversed.

Mr. Horace Avory for the complainants explained that the object of the complainants was to obtain the ruling of the Chief Magistrate as to the meaning of section 212 of the new London Building Act of 1894, which came into operation at the beginning of the present year. It was an Act to repeal the various Building Acts of the Metropolis and to simplify matters. Unfortunately, simplification had not been one of the results up to the present. In 1890 his clients entered into a contract with the then Duke of Bedford to take the lease of a piece of land in what was now called Tavistock Street, but which was at that time a mews, at a ground-rent of 2,000*l.* a year. They undertook to erect buildings on the land, after taking down the then existing structures, and erect certain flats in accordance with plans approved by the Duke of Bedford, or his representatives, and complete them before June, 1895. The building was to be erected in blocks. One block had been erected, and it was now proposed to go on with the erection of the other blocks. The complainants had paid since 1890 2,000*l.* a year for the land. They had given notice to the surveyor of their desire to finish the building, and he had intimated that it now came under the new Act. The importance of this to the complainants was that under the new Act the Council could require a much larger area of air space than they could under the earlier Acts. Therefore, if the contention of the Council were good in law the complainants would have to curtail the size of their buildings, and there would be a corresponding reduction in the rents to be obtained. There were two questions to be decided—(1) Whether the building the complainants proposed to erect was in progress when the new Act came into force at the beginning of the year; and (2) whether, supposing it was not a building in progress at the time, it was not a building which had to be carried out under a contract entered into before this new Act. In support of his argument Mr. Avory quoted the following sections of the Act:—(Section 210)—“A building, structure, or work erected or constructed before the commencement of this Act, to which no objection could have been taken under any law then in force, shall (subject to the provisions of this Act as to new buildings or the alteration of buildings) be deemed to be erected or constructed in compliance with the provisions of this Act.” (Section 212)—“Notwithstanding anything contained in this Act, a building, structure, or work which has been commenced before and is in progress at the commencement of this Act, or which is to be carried out under any contract entered into before the passing of this Act, may be completed subject to and in accordance with the provisions of the Acts relating thereto as in force immediately previous to the passing of this Act.” He added that during the present month the Council had consented to the addition of bay windows and balconies to the building. Evidence was then given as to the agreement between the complainants and the Duke of Bedford.

Mr. Freeman, for the County Council, said the case was one of very great importance, as it was the first under the new Act. He contended that the buildings it was now proposed to erect were new buildings under the new Act. It was quite true that block A had been erected, but that did not throw a protection over blocks B, C and D. He submitted that they were separate buildings, and that the agreement between the complainants and the Duke of Bedford was not a contract within the meaning of the Act. It was obvious that the duke and the complainants intended from the first to treat these blocks as separate buildings. Under the agreement block A was to have a lease given to it directly it was finished, and so on with the others. If Mr. Avory's contention were correct much inconvenience would be caused, and work might be delayed for ten, fifteen, or even twenty years.

Sir John Bridge remarked that there were two grounds on which Mr. Avory argued that he ought to give a decision in favour of his clients. The first was that the whole of these four blocks were one building which had been commenced and was in progress at the commencement of this Act. He was inclined

to think that Mr. Avory was wrong on that point, but it was not necessary to decide that. The great point to be decided was whether this was a work to be carried out under a contract passed before this Act. In his opinion it was, and the building came under the old Act. He must give to each word in the Act its ordinary meaning and its ordinary construction. It might have been better if the section he was asked to decide upon had been made clearer; but, as he said before, he could only give to words their ordinary construction, and his decision was in favour of Mr. Avory's contention.

Mr. Avory asked for costs, as the complainants had had to come for an interpretation of the County Council's private Act, and were found to have been right. Sir John Bridge said he did not think he could allow costs in a case of the kind. Mr. Freeman intimated that the case would be taken to a higher court.

TESSERÆ.

The Temples at Pæstum.

FEW buildings are more familiar than the temples of Pæstum, yet the moment when the traveller first comes in sight of works of untouched Hellenic skill is one which is simply overwhelming. Suddenly, by the side of a dreary road, in a spot backed indeed by noble mountains, but having no charm of its own, we come on these works, unrivalled on our side of the Adriatic and the Messenian Strait, standing in all their solitary grandeur, shattered indeed, but far more perfect than the mass of ruined buildings of later days. The feeling of being brought near to Hellenic days and Hellenic men, of standing face to face with the fathers of the world's civilisation, is one which can never pass away. Descriptions, pictures, models, all fail. They give us the outward form; they cannot give us the true life. The thought comes upon us that we have passed away from that Roman world out of which our own world has sprung into that earlier and fresher and brighter world by which Rome and ourselves have been so deeply influenced, but out of which neither the Roman nor the modern world can be said to spring. There is the true Doric in its earliest form, in all its majesty. The ground is strewn with shells and covered with acanthus leaves, but no shell had suggested the Ionic volute, no acanthus leaf had suggested the Corinthian foliage. The vast columns, with the sudden tapering, the overhanging capitals, the stern square abacus, all betoken the infancy of art. But it is an infancy like that of their own Hēraklēs, the strength which clutched the serpent in his cradle is there in every stone. Later improvements, the improvements of Attic skill, may have added grace. The perfection of art may be found in the city which the vote of the divine assembly decreed to Athēnē; but for the sense of power of simplicity without rudeness the city of Poseidōn holds her own. Unlike in every detail there is in these wonderful works of early Greek art a spirit akin to some of the great churches of Romanesque date, simple, massive, unadorned like the Poseidōnian Doric. And they show, too, how far the ancient architects were from any slavish bondage to those minute rules which moderns have invented for them. In each of the three temples of Pæstum differences, both of detail and of arrangement, may be marked, differences partly of age, but also partly of taste. And some other thoughts are brought forcibly upon the mind. Here, indeed, we feel that the wonders of Hellenic architecture are things to kindle our admiration, even our reverence; but that, as the expression of a state of things which has wholly passed away, nothing can be less fit for reproduction in modern times.

The Gothic Revival.

It was the love of Mediæval lore, of old English traditions of border chivalry which, by the magic power of association, led the more romantic of our sires and grandsires first to be interested in Gothic architecture, and then to discern its beauties. Horace Walpole, both as an author and a virtuoso, may be said to have sown the seeds of this taste, but it is to the writings of Sir Walter Scott that we must refer its further development. Even in his day it was but a sentiment. The grossest ignorance still prevailed concerning the practical adaptation of a Mediæval spirit to masonry and sculpture. One of the chief merits of the Pointed style is, that the origin of every decorative feature may be traced to a constructive purpose. Thus the stone groining over a cathedral aisle not only presents a vista of graceful curves to the eye of the spectator, but covers the area below it with an almost imperishable roof. The earliest promoters of the Gothic revival appreciated the superficial effect of such features without recognising the utility which justifies their adoption. Accordingly the glories of the “fretted vault” were not unfrequently imitated in lath and plaster. Nor were there men of taste wanting to praise the wretched parody. Pugin was the first who deftly expounded the true principles of what he not inaptly named Christian art. No man of his day was better fitted to undertake the task. He

was by profession an architect. He wrote with considerable ability. He entered on the subject with the full information of an earnest student, and with the zeal of a religious enthusiast. There was, however, one drawback to his efforts. He blended his theological convictions with his theories on art, and the result was that the two became identified in the public mind. He had both causes deeply at heart, but he would have served both better by keeping the subjects distinct. As it was, he sometimes offended the communion he had left by needless allusions to his faith and sometimes alarmed his fellow-churchmen by the undue importance which he attached to the style of ecclesiastical decoration. Time has proved that the revival of Gothic architecture is due no more to the teaching of Rome than that of Geneva, and at the present day the Pointed arch is almost as much in vogue among Dissenters as it is with Ritualists. The decision of a Parliamentary Commission in 1836—that the new houses were to be Mediæval in character—gave great impetus to the growing taste; and though the Palace of Westminster may not have realised the highest qualities of the architecture which it is popularly supposed to represent, it has, at least, proved an excellent school for the encouragement of ancient art. It has educated many a sculptor, stone-mason, metal-worker, decorator and cabinet-maker, who would otherwise have grown up ignorant of every phase of ornament save that which had reached him by a perverted tradition. Barry, to whose talent are due the merits of the general design, wisely entrusted to Pugin the fashion of those details which were to enrich his structure. Judged by the light of a maturer taste they may appear deficient in artistic quality. But it is certain that at that time no one could have designed better.

Vastness in Architecture.

In historic art of all periods we find certain picturesque features ever recurring, such as colonnades, arcades, buttresses, recessed openings to massive walls, towers, spires, domes, mouldings and sculptures that grow out of the mason's art. It is by the universal adoption of the same, or analogous, means to attain the same artistic results that the unity of the art is declared. The methods employed may vary at different times, yet the quality aimed at is much the same. Take, for example, the various means adopted at different times to render vastness or sublimity. At one time it is the vastness of mass in the Pyramids, and the impression of solidity and durability that they are so well calculated to give. At another time it is the vastness of the rock-cut tombs and temples (as the Elephantia rocks at Bombay) that chill the marrow with their mysterious gloom, huge columns and colossal deities counter sunk in the rock. At another the vastness of a gigantic columnar edifice that shall give the sense of infinite space, as at Karnak; at another, the ring of monster monoliths at Stonehenge; at another, the vastness of grand scales in the Coliseum at Rome; at another, the vastness of height in the French cathedrals; at another, the vastness of proportions, as at Seville, or Milan, or St. Peter's at Rome; at another, the vastness of long-drawn aisles with monotonous columns and flat roofs, as in the Italian basilicas, or Ely and St. Albans. In most of these examples it is sheer weight and vigour of masses that is employed as an attribute of expression—the undivided weight of solid stone, colossal scale, broad sunshine and unrelieved gloom. The Hypostyle Hall at Karnak is one vast oblong, 380 feet long by 170 feet wide, that has 116 huge columns, and that covers more than 88,000 feet. No artist has been able to reproduce its form so as to convey to those who have not seen it an idea of its grandeur. A flood of light beats down from the clerestory formed by the taller central piers, and the smaller pillars fade away into deep obscurity. Or to speak of that characteristic French way of using vastness of height, in those "soaring miracles of stone" at Beauvais, Le Mans, Tours, &c. And here, though this be the leading purpose of the architect's design, it is combined with other manifest attributes of mechanical power, fertile invention and that conformity to rule which governs the constructive side of perfect architecture; while the higher and spiritual side is proclaimed in a bright imagination, noble proportions, sublime audacity, and the restless, half-sad, half-gay humour of a spirit that yearns after the unattainable.

Philippe le Bel's "Hystoire Saynte."

In the Burgundian Library of Brussels is a Bible written on vellum, with illuminations in gold, silver and colours. It belonged to Philippe le Bel, King of France. For *naïveté* of design, utter neglect of perspective, contempt of probabilities and anachronism of costumes, the vignettes are unmatched. Imagine Elijah mounting into heaven in a long cart, much resembling that in which criminals are conveyed to the guillotine in a highly decorated state, with tongues of bright red flame symmetrically disposed along the sides and wheels. This eligible vehicle is drawn by a horse which a London costermonger would be ashamed to own, lashed, however, into a state of extreme excitement by the efforts of a singularly ill-favoured angel in dirty white garments, who bestrides him

to his evident discomfort. The prophet himself sits meekly in his chariot of triumph, with lifted hands, contemplating the Pegasus by whose efforts he is to reach the favoured and celestial regions, indicated by a line of intense ultramarine blue, and wearing on his face (by some curious and novel process presented to the gazer's view in defiance of all the laws of nature) a very natural and excusable expression of doubt and distrust of ever getting there. The whole concern is just rising, in a highly perilous and perplexing manner, from a pale green ground, upon which, at the foot of a rock, kneels Elisha, decidedly astonished, as he well may be. Like his master, he has performed upon himself a *tour de force* of unparalleled cleverness, for, as he kneels, his limbs, from the knee downwards, are stretched out by his side instead of behind him, a position quite incompatible with modern ideas of anatomy. This is one among a thousand similar examples. Solomon is depicted staring with a look of indescribable horror and dismay, mingled with contemptuous surprise, at three flame-coloured cherubim, who are huddled together in a most undignified heap in a corner of the picture. The monarch is habited in gorgeous robes, blue and gold, and sits upon a hard chair, with an uncomfortably low canopy, in a room, or rather on a sort of background of a mosaic pattern in black, red and gold. But what shall we say of the cherubim? Heads there are indeed, and wings, but little else save a brick-dusty mist; the heads aforesaid being at least twice the size of Solomon's, and the points of the wings serving as feet, or at least supports, to them. These celestials bear a decidedly stupid countenance and look somewhat like schoolboys afraid of a flogging, and neither they nor the wise king seem to know what to make of each other, at which no sensible individual can be astonished. The two angels sent to Sodom and Gomorrah are seen approaching a pinky town, of which the walls and ramparts just reach their heads; the walls (garnished with towers like pepper-boxes) are ornamented with lambent tongues of fire, in the midst of which, and attached to the walls by some mysterious agency, hangs in a very animated attitude a wild, little, black imp, supposed to represent the promoter of evil hovering over the devoted city. One of these vignettes occurs every fourth or fifth page, and in the others every capital letter is blazing with the richest and most elaborate designs, and stiff with gold leaf. And round many a page are rolled the most graceful patterns of leaves and branches in fanciful wreaths, of an elegance and delicacy which furnish a most singular contrast to the agonising stiffness and wooden outlines of the human figures.

Ventilation of Hospitals.

So wide is the difference between the wants of a ward filled with the sick and wounded with respect to ventilation, and the wants of every other kind of apartment in which people in health congregate or lodge, that the means which are found sufficient to maintain the purity of the one fail in maintaining the purity of the other; and an architect who has not submitted to make himself familiar with the state of the atmosphere in, for example, the crowded wards of a badly constructed hospital, at those hours of the day and night when the admission or the exclusion of air is left to the nurse and patients, is ill-qualified to form an opinion on ward ventilation. Until the architect will consent to give his organ of smell a few minutes' practical training, about six or seven o'clock in the morning, in a crowded surgical ward, he can never realise the importance of a truth which can hardly be enunciated with too great emphasis—that not merely must a ward, if it is to be kept sweet, be ventilated in the ordinary sense of the term, but it must be so ventilated as to secure for it the constant renewal of the contained air, the displacement of the foetid effluvia ever being emitted from the bodies of the sick and wounded, and the substitution instead of air not drawn from cellars, corridors and passages, but admitted direct from the store of the unpolluted heavens.

Eastern Art.

The superstition of the East seems to have thought human beauty too mean an ornament for a god. Human beauty requires the human form; but the Eastern religion and art, unable to show superior strength by Herculean muscles, resorted to the rude expedient of indicating it by gigantic size or by many hands; and the sculptor who could not represent divine intelligence in a face attempted to express it by four heads. There are traces of these notions in the Grecian mythology sufficient to show its descent; but at last, after art had been toiling in India, in Persia and in Egypt to produce monsters, beauty and grace were discovered in Greece. It is probable that the quantity of labour employed in England on docks, canals and other useful works during fifty years was greater than that employed on all the boasted works of Asia, from the Wall of China to the Pyramids. To pierce a country in all directions with canals was, in truth, a greater work than any of them. But our public works being dispersed, unornamented and for purposes of obvious use, want the qualities that impose on the vulgar imagination.

NOTES AND COMMENTS.

THE election of Mr. GEORGE CLAUSEN as an Associate of the Royal Academy is satisfactory. As a painter he is slow in production, and it must be said he has avoided the common ways of gaining notoriety. When Mr. CLAUSEN left the South Kensington Training School he promised to be one of the foremost decorators of our time, and when he joined an industrial establishment as designer he seemed to be in his right place. If he abandoned that class of work there was an excuse for him which does not avail in nine-tenths of the cases where designers are ambitious to become painters. Mr. CLAUSEN possesses pictorial ability. His drawings and paintings do not appeal to the multitude, for he is indifferent to that prettiness which is better adapted for boxes of confectionery than for pictures, but which is admired by publishers, dealers and their patrons. Yet we are not certain that Mr. CLAUSEN has yet discovered his line. He has the courage to be realistic and sympathy with the pathos of humble life. He shows himself to be the worthiest follower of BASTIEN LEPAGE, but now that he has gained position it would be well to be more true to his own genius.

IN the "Sketches of Durham," by the Rev. G. ORNSBY, we read:—"There is every reason for supposing that an apse terminated the eastern extremity of the cathedral as finished by the Norman architects. Mr. RAINE supposes the choir and aisles each to have had apsidal or semicircular terminations, but there appears much plausibility in the reasons which Mr. BILLINGS alleges for his suggestion, that the aisles were carried round the apsidal ending of the choir." BILLINGS'S theory of the ambulatory has generally prevailed, but a discovery by Canon GREENWELL a few days since proves that Canon RAINE made a nearer guess to the original arrangement. While some men were engaged in the excavation for a heating apparatus at the east end of the south aisle, Mr. GREENWELL perceived that the outer wall against which they were working was ashlar faced, and as such masonry was strange in foundations, he asked the men to dig a little to the east, when he discovered that the aisle had an apsidal termination and did not form one side of an ambulatory as was generally believed. The discovery led to a similar excavation being made in the northern aisle of the nave, which was also found to have an apsidal termination. The wall of the apse in each case is of immense thickness and solidity. It is planned in semicircular form on the inside and square on the outer or eastern side, and measures from its curved face to the square face no less than 12 feet. Canon GREENWELL considers the solidity of this foundation work implies a superstructure of heavy masonry, but as to what CARILEPH intended in this direction nothing is disclosed. The excavations are in progress, and it is hoped that the apsidal end of the choir will also be discovered, and then the ground plan of CARILEPH'S east end can be traced.

AT the annual meeting of the managers of the London Board Schools on Tuesday the growth of defective eyesight among the pupils was mentioned, and it was suggested that a special inquiry into the causes should be undertaken. The Secretary of the Education Department, who was present, told them that a committee had been appointed with the same object, and in addition to the services of Mr. SHARPE, who was the senior inspector of schools, and of some of the ablest officers of the Department, Mr. BRUDENELL CARTER'S were also available. The inquiry should be comprehensive: Twenty years ago it was assumed that the children suffered through the inadequate and haphazard lighting of schools and the awkwardness of their position when writing, owing to the defects of the desks. Although the rules prescribed for the size and position of windows are observed, and the angle of the desks is different, yet there seem to be as many weak eyes as formerly. It cannot be said any longer that either architects or school furnishers are responsible for the defects. It might be an advantage if children were not obliged to employ white paper when writing, and if their books were not printed on white paper. When Sir JOHN MACNEILL, the engineer, printed his "Earthwork Tables," which forms the largest volume of its

class, he consulted Mr. BABBAGE, the mathematician; about the best means to avoid fatigue to the eyes of calculators. After experiments it was ascertained that with toned paper the pages of figures could be consulted for many hours with ease. The type used in them was sharply cut. Much of the type used in cheap school books imposes a strain on the eyes, but the worst of all is the type used in printing the periodicals which are most often read by children in Board schools.

THERE are so few opportunities for erecting buildings on a large scale in Ireland, there is a risk that architecture may soon become like one of the lost arts of the Celts, which are so often deplored. Although it is only on a lunatic asylum, the proposed expenditure of 200,000*l.* must be satisfactory intelligence for architects as well as for contractors and building workmen. The competition for the Portrane Asylum, near Dublin, was limited to fifteen Irish architects, but as three retired, only twelve sets of plans were sent in. The Board of Control obtained the aid as assessors of three English experts, viz. Sir A. MITCHELL, Mr. G. C. HINE, architect, and Dr. MOODY. They came to the conclusion that the designs marked "Luna," "Mens Sana" and "Aspect" were equal in merit. They were prepared by Mr. GEORGE C. ASHLIN, Messrs. RAWSON CARROLL & BATCHELOR and Mr. W. KAYE PARRY. There are two bodies who have an interest in the undertaking, viz. the Board of Guardians and the Board of Control for Asylums, but we believe the final selection will depend on the latter. The estimates of cost which are being prepared will of course have an influence on the decision. It is not often three out of twelve plans are placed so high, and the award suggests that in spite of the dearth of opportunities for practice the Irish architects are skilful in planning, and with a class of buildings of which the examples in their own country are only adapted to serve as warnings of defects.

AMONG the paintings added to the Luxembourg collection is the *Benedicite*, by Mr. J. H. LORIMER, the Scottish painter, and the *Cigarreras*, by Mr. WALTER GAY, the American. From a Fleming M. BAERTSOON, a *Canal Scene*, and from M. LUND, a Swede, a *Landscape*, have been also purchased. Paintings by the French artists, MM. CORMON, CAZIN, GENEUTTE, TATTEGRAIN, PERRET, AGACHE, GUIGNARD and BOUVOT are also among the additions. There is more room for statuary than for paintings in the Luxembourg, and six new examples now appear, besides some that belong to industrial art.

THE French painter of rural scenes, M. GASTON GUIGNARD, has succeeded, it is said, in the employment of water-colours on the sort of canvas commonly employed in oil-painting. This is done without any coating which would prepare the surface. But M. GUIGNARD employs a varnish which, although not adapted for use on paper, increases the effect of the colours in several ways, and especially imparts brilliancy to them. The French *aquarelle* differs from the English drawing on coarse or smooth paper, and is better adapted to be utilised for the production of mysterious effects. Although M. GUIGNARD'S treatment may find many admirers in France, we doubt if it will achieve conquests in England, where the old-fashioned ways of applying colours are not obsolete.

SOME of the French papers have been reviving the legend about the burial-place of ALEXANDER THE GREAT. Not long since a fine sarcophagus was found, which is now in Constantinople, and from the inscriptions it was declared to be the tomb of the conqueror. But there are many who believe in the tradition that ALEXANDER'S body was carried from Babylon to Alexandria and buried beneath a hillock. In order to keep the spot sacred MEHEMET ALI erected a mosque over it. One of the walls, it is said, has settled, and a glimpse is obtainable of the subterranean part, that contains massive masonry, which, it is concluded, must enshrine ALEXANDER'S tomb. The Egyptian Government will not allow any exploration to be undertaken. The story may be only another of the imaginary grievances which are supposed to arise out of the English control in Egypt.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

A MEETING of the Institute of Architects was held on Monday evening, Mr. Aston Webb, vice-president, in the chair.

Mr. J. A. STRAHAN, barrister, read a paper on

The Legal Position of Architects in Relation to Certificates and Awards.

Mr. Strahan in his preliminary remarks noticed there had been a tendency to settle disputes outside of the Law Courts. The former system of giving a salary to a judge instead of levying fees had made a change. The need of settling disputes that arose under contracts without having recourse to litigation had long since been felt by architects. Two methods had been suggested: one in short might be called settlement by certificate, the second by reference to a third person—in other words arbitration. In settlement by certificate it must be shown in the contract as a condition precedent, or the contractor could take no action. Even then certificates given during the progress of the work only enabled a contractor to claim the amount certified for. A final certificate could include extras, but it could not hinder a final readjustment in the case of extras improperly ordered. The certificate when a precedent condition, to right of action, on the part of a contractor, constituted a final certificate conclusive both against the contractor and also in favour of the contractor. Arbitration was not necessarily made a condition precedent to the right of action. If made a condition precedent, there was no alternative but to arbitrate, and the Courts could do nothing till an award was made. In case of disputes the position of the architect was that he acted as a certifier or as an arbitrator. In arbitration the architect acted in a judicial capacity, in certification or valuation the architect was merely the skilled servant of his employer. The Courts had power over an arbitrator, but no power over a certifier. As certifier an architect could proceed as he liked. He was not bound to hear any evidence on either side. His decision, though erroneous, if *bona fide* and honest would be valid. The architect would be liable to his employer for the result of his certificate, but though an action was taken by the employer it would not shake the certificate, nor would there be liability from the architect to the contractor. Mr. Strahan then considered the advantages and disadvantages of each method, viz. certification and arbitration. He gave his reasons for thinking that though it probably depended in some cases on the merits of any actual contract, in a general way, no doubt, settlement by certificate was the best for parties all round.

The CHAIRMAN in inviting a discussion intimated that the Institute would at an early date revise the conditions of contract.

Professor KERR proposed a vote of thanks to Mr. Strahan. The result of the reading of the paper would be to create alarm. As architects, they considered it was unfair for an architect to be an absolute judge without appeal. An architect gave his decision loyally, and it was as a rule loyally accepted, for the architect as a judge was absolutely impartial. Under litigation, lawyers had no half-way. One party must be wholly right and the other party wholly wrong. In arbitration, each party appointed their own agent, and these appointed a third. These three talked the matter over and an equitable settlement was arrived at.

Mr. E. T. HALL seconded the vote. Many great corporations preferred to have the architect as final referee. No final certificate of completion should be given. They should leave contractors to the Statute of Limitations. The Builders' Institute were in favour of that procedure.

Mr. WOODWARD said an architect should not be judge in his own case. A builder should have protection against an architect in case of an architect's negligence or ignorance.

Professor BANISTER FLETCHER considered that no builder should have a responsibility hanging over his head for years, and the architect have none. An architect was not a third party in a dispute. He held a fiduciary position, and should hold liability equally to client and contractor, or else have no liability to either.

Mr. WM. WHITE and Mr. RICKMAN supported the vote, which, having been passed, the meeting adjourned.

Mr. Fellowes Prynne has designed a new carved case for the organ at St. Mary Church, near Babbacombe Bay, which will be carried out in oak.

WELLS CATHEDRAL.

AT Toynbee Hall on Sunday night Mr. Edmund Buckle, diocesan architect for Bath and Wells, contributed a description of Wells Cathedral to the course of Sunday evening lectures on English cathedrals now being held at the hall. With the aid of the oxy-hydrogen lantern he gave a large number of interesting views of the more prominent features of the cathedral, and described its architecture in detail. He observed that Wells was by no means the grandest or most magnificent of English cathedrals, but it had a peculiar interest of its own and contained many striking features, noticeably in its statuary. It was one of the few cathedrals which had retained its Mediaeval surroundings. In close proximity to it were a number of buildings with which it was connected and which, for the most part, were still used for the purposes for which they were originally intended. The actual foundation of the cathedral was of a very uncertain date—the year 700 was given by tradition. All that was really known was that a portion of the older building came into existence at the time of Edward the Elder. The font was the oldest remnant of the earlier church, and dated from the twelfth century. All the earlier portions were in a style known as the local Somerset style, the later addition on the eastern side being in the Early English style, and of a far more decorative character. A remarkable feature was the St. Andrew's arches supporting the main central tower. At the extreme east was a large window known as "the golden window," on account of the large amount of gold and green glass used in it. It still contained the original glass. The clock was another feature of interest. It originally had wooden works, which had now been removed and could be seen in working order at South Kensington. It dated from the fourteenth century. The sculpture on the western front of the cathedral was very beautiful and elaborate. There was also a lady chapel, a chain gate, a vicar's close, and a large number of very ornamental chantries. The lecturer concluded by describing the bishop's palace adjoining the cathedral, which, he said, was one of the few remaining specimens of a thoroughly-protected and fortified bishop's house to be found in this country.

ST. PAUL'S CHURCH, MORLEY.

THE new nave of St. Paul's Church, Morley, has been dedicated. The edifice occupies the site of the old church, which was consecrated in 1877 by the Bishop of Ripon. The church had only sittings for 275 persons. The building committee sought the advice of Mr. G. H. Fellowes Prynne, F.R.I.B.A., of Westminster, who submitted a report to the effect that the old building could not be enlarged in any way to meet the requirements of the district. Mr. Prynne prepared plans of a new nave, with side aisles and transepts, to afford accommodation for 800 persons. The complete scheme, however, includes the erection of a chancel, a tower with spire and a baptistery. The cost of the whole scheme is estimated at 10,000*l.*, and the cost of that portion which has this week been completed is estimated at 6,300*l.*

The new church is a large and commodious stone building of the Early English Transitional Period. The nave, which is entered under a massive archway, is lofty and broad, 95 feet in length and 28 feet in width, divided into five bays, the nave itself giving accommodation for 446 adults in front of the chancel and altar. The roof is of ribbed barrel vault frame. Massive stone pillars support the arches of the nave, the main spandrels over the arcade being surmounted by clerestory quatrefoil windows. The north and south aisles abut against the three western bays of the nave, the northern aisle being reconstructed from the north aisle of the old church. The porch leading to this is the old porch rebuilt.

A double transept is thrown out on either side terminating in a chancel aisle. The north transept consists of a portion of the old nave rebuilt in a new position and terminates in choir-vestry and organ-chamber. A western exit is supplied to each transept. A clergy and choir vestry, with a good sized heating-chamber under, is placed at the eastern side of the choir-vestry and is connected with it by a door, both entrances having separate entrances for a porch and to the church. The materials of the old church have been re-used to the utmost possible extent. The seats in the nave and transepts consist of chairs.

The hot-water system of heating the church has been adopted, the apparatus being supplied by Mr. de Ridder, of Liverpool.

The tower and spire has been designed to be placed at the south-west end of the south aisle, and it may be built in future without injury to or interference with the new church. The whole of the work in connection with the erection of the nave has been carried out in a satisfactory manner by Messrs. J. & J. Sugden. Mr. J. Wornell has been clerk of works, and Mr. R. H. Hale quantity surveyor.

ST. GEORGE'S CHURCH AND PARSONAGE, BARROW-IN-FURNESS.

E. G. PALEY'S CHURCHES.

IT is not always possible to determine the proportion in which the members of a firm of architects contribute to the preparation of designs. The individuality of the late Edward Graham Paley was, of course, merged in the work of Paley & Austin, of which there are a great many examples. It is right, however, that a younger generation of architects who are acquainted with the firm's churches should be aware that Mr. Paley for years was without a partner, and was able to make a reputation as an architect. We have therefore produced views of a few of the Lancashire churches which were produced from his designs. It will be observed that they were intended to meet different requirements, and most of them were "cheap churches," but they all have a distinct character.

When the church at Barrow-in-Furness was erected the town had not attained its present importance. The money for the building was given by the Duke of Buccleuch and the Duke of Devonshire. The church had room for over six hundred people, and cost about 4,000*l*.

The church of St. Mark, Preston, is the largest, for it can accommodate about a thousand worshippers. The nave, it will be seen, is large, measuring 91 feet by 41 feet, with a chancel of 36 feet by 27 feet 6 inches. On one side of the latter are the tower and vestry, and on the opposite side the organ chamber. The walls are of Longridge stone lined in the interior with red bricks. The principal entrance is by a porch at the west end, over which is a large five-light window.

The church at Over Darwen was erected at the expense of two individuals. The stone was from local quarries. It cost about 6,000*l*.

Trinity Church, Bury, was erected on a site given by the Earl of Derby. In designing it provision was made for future enlargement. The nave measures 75 feet by 25 feet, chancel 28 feet by 22 feet, and the height to ridge is 43 feet.

A bequest of 12,000*l*. for the building and endowment of a church, parsonage and schools was the origin of Allithwaite Church. All that could be expended on a church to hold three hundred and fifty people was 2,500*l*.

The *Lancaster Guardian* of Saturday last contains the following interesting memoir of Mr. E. G. Paley:—

Mr. Paley was not a native of Lancaster, though he has for nearly sixty years been closely identified with the town. He was born in September, 1823, at Easingwold, near York, and was the fourth son of the Rev. Edmund Paley, vicar of that place, and grandson of the Ven. Archdeacon Paley. He was principally educated at Christ's Hospital, London, and whilst there had the honour of being presented, as the grandson of Archdeacon Paley, to the Duke of Wellington, who gave him a golden guinea, which memento of his interview with so notable

a person Mr. Paley long retained in his possession. He came to Lancaster in October 1838, and became a pupil of the late Mr. E. Sharpe, by whom, at the completion of his articles in 1845, he was taken into partnership. The firm speedily acquired an extensive practice, the excellence of their designs and the thoroughness with which the works undertaken by them were carried out enabling them to attain a reputation second to no other firm of architects in the North of England. More particularly was this the case in ecclesiastical architecture, and there is probably no other architect in the country who has for so long a period occupied the prominent position enjoyed by Mr. Paley in regard to Church architecture. Monuments to his skill and versatility in designing and to the excellence of workmanship, for which he early acquired fame, are to be found all over Lancashire and Yorkshire, and there are few dioceses in the country which do not contain one or more churches erected under his supervision.

In 1851 the late Mr. Sharpe retired from the firm, and from that time up to 1868 Mr. Paley carried on business on his own account, and during this period he designed many new churches in Lancashire and Yorkshire, as well as other public buildings. Perhaps the most noteworthy specimen of the work carried out by him at this time in the Lancaster district is St. Peter's Church, with the presbytery, schools and convent, which were erected in 1859 at a cost of 15,000*l*. Amongst the public buildings designed by him during this period, and erected under his supervision in the immediate neighbourhood are the Royal Albert Asylum, the Royal Grammar School, the Cemetery buildings, the old Savings Bank, the Waggon Works, and many smaller buildings of a more or less ornate character.

In 1868 Mr. Paley became associated with Mr. H. J. Austin, and at a still more recent date Mr. H. A. Paley became a member of the firm. Since 1868 the firm have been responsible for the architecture and construction of no less than forty churches in various part of the country, many of them in the immediate neighbourhood of Lancaster. Though, however, ecclesiastical architecture may be said to have been the chief character of the business carried on by the firm, their efforts were not infrequently directed in other channels. The mansions of many of the principal landowners in Lancashire and Westmorland have either been built or at one time or another undergone restoration and renovation at their hands, amongst other county residences to which additions and alterations have been made in comparatively recent years being those of the late Lord Winmarleigh, the late Earl Bective, Sir J. Ramsden, the Duke of Devonshire, Sir Gilbert Greenall and Mr. John Fell, whilst many schools and public buildings have been erected under the supervision of the firm. One of the latest works in which Mr. Paley took the greatest interest was the erection of the Storey Institute at Lancaster, a building not

only architecturally beautiful and an ornament to the town, but remarkably well adapted to the purposes for which it was designed. In the matter of ecclesiastical architecture it may be mentioned that Mr. Paley's firm have designed and erected episcopal churches costing 300,000*l.* in the Manchester diocese alone. Mr. Paley was a member of the Council of the Royal Institute of British Architects, and was this year one of the examiners of the Institute.

Although from time to time taking a very active part in the management of many institutions and associations of a more or less public character in the town, Mr. Paley seems to have steered clear, except for a very brief period, of actual municipal work. For three years only he was a member of the Corporation. For many years the deceased gentleman discharged the duties of County Bridgmaster of the Hundred of South Lonsdale, and in that capacity regularly presented reports to the Court of Quarter Session as to the repair and maintenance of bridges in this district. The new bridge over the Lune at Caton was designed by him, and was carried out under his supervision by Sir Abraham Woodiwiss, of Derby.

Mr. Paley took the greatest interest in archæological and antiquarian researches, was for many years a member of the Royal Archæological Society, and so far back as 1858 he, along with the late Mr. E. Sharpe, conducted the members of the Society through the parish church, the castle and to various spots of antiquity and interest in the neighbourhood. He was also a member of the Cumberland and Westmorland Archæological Society, and took part in many of the excursions and meetings held by this Society in recent years. Locally there are few public organisations of which Mr. Paley was not at one time or other an active member. He was one of the founders of the Lancaster Choral Society, and being himself an accomplished musician, has always taken a keen interest in the progress of the Society and in the culture of music in the town. For many years he was a director of the old Athenæum Company, and he was one of the promoters of the recently defunct Philosophical Society. In the work of the old Mechanics' Institute the deceased gentleman was a very active participator, taking an especial interest in the School of Art, for many years held in the Institute. He successively filled the offices of secretary, treasurer and president of the school, and at the time of his death was a member of the committee of the Storey Institute, taking an especial interest in the culture of art as applied to industries. He was also for many years a member of the Lancaster Charity Trust, having been elected in October, 1879, in succession to the late Mr. Richard Hinde. In early life Mr. Paley was a prominent oarsman, and along with Mr. Sharpe was chiefly responsible for the formation of the Lancaster Rowing Club. In 1844-47 a crew composed of Messrs. Sharpe, Paley, T. Austin and Buck achieved some notable victories over crews from Liverpool, Chester, Preston and Fleetwood. Throughout his busy life Mr. Paley continued to take an active part in the management of the club, and at the

Jubilee banquet in October, 1893, humorously offered to "find a crew of old 'uns to compete against the young members." Mr. Paley married in June, 1857, Fanny, the third daughter of the late Mr. F. Sharpe, of Knutsford, Cheshire, who, with one son and three daughters, are left to bewail his loss.

Mr. Paley was an active member of the central committee of the Royal Albert Asylum; in fact, he was one of the original ten members of the committee who held their first meeting on November 14, 1864, to consider "the offer of Mr. James Brunton, of Morecambe, book-keeper, to give the sum of 2,000*l.* towards the establishment of an asylum in or near Lancaster for the reception, care and training of idiot children, and to confer on the advisability of making an attempt to establish such an asylum, and as to the practicability of raising funds for that purpose." At that meeting there were present Dr. E. D. de Vitre (chairman), Messrs. Ross, Harrison, Sharp, Howitt, Milner, Brunton, Seward, Paley, Grant. It was then resolved that these gentlemen, with Mr. Thomas Storey and Mr. Wm. Roper, should form the provisional committee. When the project began to take shape, and plans for the building were talked of, Mr. Paley retired from the committee, and he was appointed architect on April 25, 1866. In May, 1878, Colonel Thornhill, on leaving Lancaster, resigned his membership of the committee, and Mr. Paley was invited to take the vacant place. From that time until his death he took a most earnest interest in the management of the institution, and he attended the last meeting of the committee on the 11th inst., though he then complained of feeling a little out of sorts. As may be supposed, there was no scheme for the enlargement or extension of the asylum (of which he was the able architect), which had not his thoughtful consideration in its incipient stages, and its oversight in being carried out seemed to have his constant and loving care. Mr. Paley will be greatly missed at the Royal Albert Asylum, he was so genial and courteous; he attended the committee meetings so regularly and he was always deeply interested in the training and progress of the patients. He was chairman of the Branch Establishment for private patients at Brunton House.

The announcement of Mr. Paley's death will come as a shock to many outside Lancaster, by whom he has been known as one of the most eminent architects of the country; but in Lancaster his decease will be deeply regretted, not merely because he was one of the foremost of our citizens, but on account of his geniality, kindheartedness and readiness to help in every good work. He was one of nature's gentlemen, always cheerful and kindly; and he was deservedly esteemed and respected by all with whom he came in contact. Immediately on the news of his death being circulated flags were hoisted half-mast at the Town Hall, Royal Albert Asylum, Ripley Hospital, Parish Church, County Club and other public buildings, and regret was very generally expressed that death had removed one who had lived so active and useful a life from amongst us. The remains of the deceased gentleman were interred on

ALLITHWAITE CHURCH.

TRINITY CHURCH, BURY.

CHURCH, OVER DARWEN.

Saturday morning, service commencing in the parish church at eleven o'clock. The Mayor and Corporation assembled at the Town Hall at ten o'clock, to pay the last tribute of respect to the memory of the deceased.

LIST OF PRINCIPAL WORKS DESIGNED BY MR. PALEY'S FIRM.

Messrs. Sharpe & Paley.

In 1845 Mr. Paley became a partner with Mr. Sharpe, and the firm carried out the rebuilding of the parish church at Wigan, new churches at Knowsley, Lever Bridge, Rusholme, and other smaller ones; new halls at Capernwray, in Lancaster, and Ince, near Chester; large additions to the County Lunatic Asylum and Castle at Lancaster, &c.

Bank, Royal Grammar School and several smaller buildings. At Barrow-in-Furness, large ship works and jute mill, schools, new bank, old railway station, &c. For Furness Railway Company, stations and hotel at Furness Abbey, Grange, &c.; hotel at Grange; mansions at Abbotswood (for Sir James Ramsden), Wennington, Dalton, Newfield Halls, Browhead, Windermere, and numerous smaller buildings, schools, parsonage, houses, &c.

Messrs. Paley & Austin.

Mr. Paley became associated with Mr. H. J. Austin in 1868, and since that date the firm have designed and carried out above forty new churches, many large and important, viz.:— Mossley Hill, Liverpool (with parsonage); Kirkby (for Lord Sefton); the Saviour's and All Saints at Bolton-le-Moors; St. Mary's, Beswick; Higher Broughton, and St. John's, Cheetham Hill, Manchester; St. Clement's, Salford; Millom; Bettws-y-

ST. MARK'S CHURCH, PRESTON.

Mr. E. G. Paley.

From 1851 to 1868 Mr. Paley practised on his own account, and designed and carried out several new churches, viz.:— St. George's and St. James's, Barrow-in-Furness; St. Peter's Catholic Church (with presbytery, schools and convent), at Lancaster; Poolstock, near Wigan; Ringley, Allithwaite (with parsonage house and schools); Aughton, St. Thomas's, Blackburn; Bradford (Holy Trinity); Bury, Bradshaw, Hoddesden, Higher Walton, Penwortham, Ince, Wrightington, Lowton, Walton, in Cumberland; Walney Island, Rossall School Chapel, Penny Bridge, Blawith, Singleton, Quernmore, Woodlands, Over Darwen, Thwaites, Livesey, St. Mark's, Preston; Stockton Heath; new Parish Church, Bolton-le-Moors; Catholic churches at Garstang and Yealand Conyers, &c. Restoration and enlargement of the parish churches of Winwick, Cartmel, Lancaster, Burnley, Easingwold, Crayke, Ulverston, Kirkby Lonsdale, Poulton-le-Fylde, Penn, Caton and others. At Lancaster, the Royal Albert Asylum, Waggon Works, new Cemetery buildings, Savings

Coed; parish church, Leigh; St. Laurence, Morecambe; Atherton, Winmarleigh; Howe Bridge, Cross Crake; Cuthbert's, Darwen; Walton, near Warrington; St. John's, Greenock; Halliwell, Daisy Hill, St. Anne's-by-the-Sea, Halton; St. Cross, Knutsford; Hutton Roof, Mansergh, Thornton, and Leck, near Kirkby Lonsdale; Largho, Scorton, Pilling, Westleigh Mill, St. Barnabas, Crewe; parish church of Dalton-in-Furness, Lower Ince, mission chapel at Scarborough, Grimsargh, Burnage, Finsthwaite, Torver, Burton-in-Lonsdale, Cloughfold, &c. Restoration (and enlargement in some cases) of the parish churches of Bowness, Heversham, Lytham, Great and Little Ouseburn, Melsonby, Alderley, Broughton-in-Furness, Penn, Bolton-le-Sands, Daresbury, Eskdale, Great Harwood, Halsall, Kirkby Malham, Llanwrst, Fleetwood, Melling, Orton, Ormskirk, Fawley, near Henley-on-Thames; Weston and Wilming-ton, near Eastbourne; Sedburgh, Dent, Colne, Prestwich, and other smaller ones. Grammar schools at Sedburgh, Skipton, St. Bees and Giggleswick. Mansions: New wing at Holker (for the Duke of Devonshire), new tower and enlargement of

Underley Hall (for Lord Bective), Thurland Castle, new wing and terraces at Fawley Court (Henley-on-Thames), Dane Ghyll, Oak Lea, Dunningwell, Chapel Ridding, Windermere; Walton Hall (new offices and enlargements, &c., for Sir Gilbert Greenall), new hall, with stables, lodges, &c., for Lord Winmarleigh. Banks at Barrow and Lancaster, for Lancaster Banking Co., and bank at Barrow, for Cumberland Union Banking Co. The Storey Jubilee Institute at Lancaster.

THE TOLBOOTH OF EDINBURGH.

THE Edinburgh Dean of Guild, Mr. Miller, in connection with the proposed extension of the City Chambers, has drawn up for the Corporation an account of the various places in which the Town Council of Edinburgh has taken up its abode during the last 500 years. The sketch contains much which will be altogether new to most Edinburgh men, says the *Scotsman*, and not a little which will be fresh even to local antiquaries. It will help to solve some points which have been a puzzle to those who have given much time to the study of the sites of the well-known houses, and the general condition of the city, of the times of the Reformation and of the Covenant.

There is one fact that must impress the reader of the record—the smallness of the Edinburgh of history and its abounding poverty. The tale of municipal life is the old Scottish story of how to support a great deal of pride and dignity on a handful of oatmeal. Verily, it was not its population, or the grandeur of its buildings, or the opulence of its inhabitants which made Edinburgh one of the renowned cities of Europe three centuries ago, nor could it be its wealth or size which drew to it the homage of the learned in so marked a manner in the days of Robertson and Scott. Census returns won't explain the fact, and the inquirer must seek for some other explanation than the mere counting of noses.

The Dean of Guild gives his story in brief when he begins by telling that "the municipal buildings of Edinburgh during the seven centuries in which their history can be traced have occupied various sites, but of all these within a stone's-throw of the same spot." This spot which has focussed our Edinburgh life is of course the church of St. Giles, the old town church. It is the only building within the line of the old walls which remains where it was 500 years ago; all else is changed, even the level of the King's High Street has been altered during the centuries. The story refers shortly to an old council chamber which stood in the end of the fourteenth century somewhere near the site of the present police chambers. Of this, the oldest of the town-houses, nothing is known. The fact of its existence is proved from an old Latin charter of St. Giles's Church. It then goes on to relate the founding of what is known as the Tolbooth of Edinburgh, the building which Sir Walter Scott has made famous in "The Heart of Midlothian." This historical building found a site in consequence of one of those accidents which happened to the town periodically—its burning by the English. In 1385 the town was burned and pillaged a little more thoroughly than usual, and of necessity the rebuilding had to be more thorough than was wont. Advantage was taken of the clearance which the fire had made to give the town a better site for its town-house than the old one on the south-east of St. Giles's. A year after the sack, Robert II. granted to the Town Council a site 60 feet by 30, immediately adjoining St. Giles's on the north-west, for a town-house or Tolbooth. The old Scottish term Tolbooth means the booth or office in which the tolls or taxes are gathered, and no better position could be found for the Tolbooth of the town than this, for it was not only beside the town church, and therefore in the centre of the town, but it was on the market-place, from which the "octroi" duties were to be gathered. At this time and onward to 1528, we have proof that the ground to the west of St. Giles's, now partly open and partly occupied by the old County Buildings, was the market square of the town. It was covered with closes in the sixteenth century and again cleared about 1817. Here, then, the Town Council built for itself a house, its southern wall being in line with the northern wall of St. Giles's, before the Albany aisle was added to the church on the north. No record of the building of the Tolbooth remains; it was probably done at two different times and by different masons, for it originally consisted of two parts—Bellhouse and Tolbooth—and these two were of so very different strengths, that while the former lasted into this century the latter was condemned as ruinous and dangerous in 1560, and had to be rebuilt. The name Bellhouse, or belfry, recalls the town belfrys of the old cities of the Low Countries, and the purpose for which they were built—that their bells might summon the citizens together, whether for purposes of peace or war. This town-house of Edinburgh, built some time in the early years of the fifteenth century, cannot have been very large—the size of the site prevented that; it was

probably not very magnificent—at least, the portion which survived into the nineteenth century was not; but it was fated to play an important part not only in the history of the town, but of Scotland. In the Tolbooth during the fifteenth century the Scottish Parliament usually sat when it met in Edinburgh; here, too, were the courts which the royal deputies held for the administration of justice; and here, in 1532, the Court of Session was inaugurated by James V. In the old Tolbooth and in succeeding municipal buildings the Supreme Court sat till the beginning of this century, when the Crown undertook the duty of finding an abode for justice. There is a strange minor key to be struck along with these more stately notes. Upstairs, statesmen were debating or judges administering justice; downstairs, velvets were being measured, or maybe the temper of sword blades tried. A Corporation which had but small funds and much to do with its money had to be thrifty, and so it let the basement of its Corporation buildings for shops; it was so in the fifteenth century, it continued to be so until the end of the eighteenth: Leonard Horner's father, for instance, was a silk mercer in the old Tolbooth.

The Tolbooth, or at least its eastern portion, the Bellhouse, was probably built by the masons who had been employed in extending the church of St. Giles in the year succeeding the great destruction of 1385; but of its building there is no actual mention in Town Council minutes until 1501, when it is noted that the tower of the Tolbooth is being built or rebuilt. The next notices are of a different kind. By the middle of the century the Tolbooth is declared to be ruinous, and the Lords of Session have left it and taken refuge in the Blackfriars Monastery in the Cowgate. Whether it had suffered when the English burnt Edinburgh in 1554, we know not; probably it had, for not a house escaped unhurt, according to the English account of the event. The Town Council repaired the house as well as funds permitted, and it was sufficiently water-tight to receive within its walls the celebrated Scottish Parliament of 1560, which disestablished the Roman Catholic and established the Presbyterian Church.

The Reformation affected the question of accommodation for municipal work in a strange way. The Town Council was strongly Protestant, and it shared the disrespect for church buildings common to the Protestants of the time; so when, in June, 1560, the Reforming party were supreme in Scotland, the Town Council found itself free to do what it chose with St. Giles's Church, in which Roman Catholic worship had been abolished. The Council resolved to screen off the eastern portion of the church for its high school, and the western end for ordinary municipal purposes—for law courts, for town clerk's chambers, and for prison accommodation—considering the rest of the nave and transepts as sufficient for worship. Times were very unsettled, and the city purse very empty; so the carrying out of this resolution was not quickly gone about. The dividing up of the church seems not to have been begun when, in February, 1562, the Town Council received a missive from Queen Mary, instructing it to take down the old Tolbooth as dangerous to the lieges, and build another. At the same time the judges of the Court of Session did their part to quicken the action of the Council by threatening to leave the town and establish the court in the town of St. Andrews. Accommodation for the court was found at once in the Holy Blood Aisle of St. Giles's; and in April the Corporation Master of Works was ordered to pull down a portion of the Tolbooth, and use timber and stones for the building of municipal offices within the western portion of the church. The idea of placing the school in the east end of the church was abandoned. The work was now actually carried out, and the Town Council took possession of the church, nor did it altogether remove the town's offices from it till 1829. Different portions of the building were utilised and for very various purposes. The western portion of the nave, which was partitioned off by a stone wall, was made into a two-storey building, and was afterwards connected with the new Tolbooth about to be built. In this appropriated part of St. Giles's Queen Mary's first parliament met in 1563, the Queen attending in great state. The upper floor was used regularly by the College of Justice, the lower was occupied in different ways at different times—now we read of the Bailie Court sitting in it, at another it is a lumber-room, in which the gallows and the "maiden" are stored. Then in the "roof of the kirk" looms were erected, and here the town's "wobsters" pursued their calling. The "re-vestry," now the Chambers Chapel, was assigned to the town clerk, who retained possession of it until 1811, and extended his domain into the north transept. A charter-house, too, was found for the town's valuable documents over the old south door, in a portion of the church taken down during the alterations of 1830. But even a worse fate was in store for the old town church, when a prison was fitted up on the north side for those taken in adultery. This portion of St. Giles's was for years afterwards used as a lock-up; in the latter days of its degradation it was known as "Haddo's Hole," from Sir John Gordon of Haddo, who had been confined in it, and when it was restored for worship in 1856, the name "Haddo's Hole"

passed to that one of the three churches to which this portion of St. Giles's was assigned.

The Town Council, although it had taken possession of so much of the old town church, did not neglect the Queen's command to build a new Tolbooth. The Queen seems to have insisted on its being done, and we can quite understand how she was impelled to press the Town Council, owing to the dislike which she, as a good Catholic, must have had to the secularisation of a consecrated building. A site for a new Tolbooth was found adjacent to the south-west corner of the church by buying up sundry houses. When the old Tolbooth had been erected, in the beginning of the preceding century, this ground to the west of St. Giles was an open space, the market-place of the town, but since then it had been covered with houses. The building was finished with remarkable expedition, money being raised by a special levy on the citizens and by the mortgaging of the town mills. The fabric of a church was utilised, too, by the purchase of a chapel of the Holy Rood which stood in the churchyard of St. Giles, but was now in ruins, its stones being used for doors and windows. The new Tolbooth, of which no drawing seems to be extant, was occupied by the Town Council in December 1564. It stood where the entrance to the W.S. Library is now, and was a building three storeys high, containing a hall in each of its two lower flats, with other rooms above, which were often let for non-municipal purposes. The lower hall was the usual meeting-place of the Town Council, the upper was used by some of the Law Courts. There the Justiciary Court continued to sit until 1809, long after the other courts had removed into the new Parliament Hall. But the new Tolbooth was used for many other purposes. It was for over seventy years the usual meeting-place of Parliament; in it the General Assembly of the Church sat occasionally, and the Convention of Royal Burghs regularly. Here the Merchant Company was inaugurated in 1681, and here it met until it acquired a hall for itself in 1691. Although it served so many and so various purposes, it appears to have been a small, shabby building. The new Tolbooth was entered from a lane which led along the west wall of the church to what, in 1560, was the churchyard of St. Giles, and afterwards became the Parliament Close. It covered this lane which passed under it through a "pend," and seems to have been built against the west wall of St. Giles. Through this gable a door was made on the level of the second storey, and this formed the communication between the portion of the municipal offices in the west end of the church and the portion in the new Tolbooth. In fact, the name "New Tolbooth" is applied indiscriminately to both, and they were looked upon as forming together the town-house. While the Town Council was building this new Tolbooth, partly in and partly outside St. Giles's Church, the old Tolbooth proper was standing in ruins, a portion of the western end having been pulled down so that its stones and timber might be used for the new Tolbooth. In ruins it remained for half a century, the Town Council being too poor to rebuild it, and needing money too much to pull it down altogether, as that meant expelling its tenants from the shops in the basement and losing the rents they paid. So matters drifted for years; the more dangerous parts of the ruins were taken down, and the tenants were allowed to make their "booths" water-tight—one of these tenants being the father of George Heriot, the founder of the Hospital. At last the Town Council moved in the matter. The country had enjoyed thirty years of peace under the rule of "our Scottish Solomon," James VI., and the town had got a shade less poor; besides, new ideas had sprung up as to the necessity of providing better prison accommodation. The old Bellhouse—the eastern portion of the old Tolbooth, which, being of superior masonry, had not been condemned along with the Tolbooth proper—had been used as a "lock-up" under the name of "The Thieves' Hole;" and in 1610—half a century after it had been condemned by Queen Mary—the ruins of the old Tolbooth were cleared away and rebuilt. To the western gable three "krames" or booths were afterwards attached. These became ruinous, and in 1678 their occupiers got permission to erect where they stood a two-storey building—the Tolbooth being five storeys high. Then the old Tolbooth was made as it appears in all the sketches which we have of it, the roof of this low house being used for years as the place of public execution.

The old Tolbooth, as rebuilt in 1610, was intended for a prison, and as such it remained to the end. It was a quaint old building as described by Sir Walter Scott, or as portrayed in Wilson's "Old Edinburgh" or M'Gibbon and Ross's "Domestic Architecture."

The next extension of municipal buildings after the rebuilding of the old Tolbooth gave Edinburgh a building of which it is still justly proud—the Parliament Hall. The project of building it is first mentioned in a minute of Town Council of March 13, 1632. It relates that "a great number of the honest neighbours of the said burgh" had conferred with the Council, and "regretting that a part of their great church,

which was appointed for divine service, should be applied to secular uses, and withal considering that the lack of convenient and fit rooms within the burgh for keeping of Parliament, Session and Council-house, and other public meetings may procure the same to be abstracted furth of this burgh," the meeting resolved to erect "such specious and necessary houses" as the Town Council shall see fit, after consultation with the most skilful architects. A subscription was at once opened to assist in defraying the cost, and James Murray, master of works to His Majesty, was appointed architect. A site was found by taking down the ministers' houses—the manses of the ministers of St. Giles's, which had been confiscated to the Crown after James VI.'s famous quarrel with them in 1586. The building cost about 10,600*l.*, 3,800*s.* of which was raised by public subscription, the balance coming out of the common fund of the city. The list of contributors with the sums given is still in the hands of the City Chamberlain. The Parliament House was finished in 1639, when Parliament met in the hall. The building was of the Gothic of the time, and consisted of the hall, running north and south, and a wing at the south end running eastward. In the hall the Scottish Parliament sat; in the wing the Law Courts. The building remained unaltered until 1810, when it was faced and the present façade built. In 1640, the year after it was finished, we find it used for a thoroughly municipal purpose, for convening the "whole neighbours" of the town to consult about "the public safety and weal"—it was a stirring time, for the Scottish Presbyterians were at open war with Charles I. In the newly-erected building the College of Justice has sat ever since, although, as was before stated, the Justiciary Court remained in the new Tolbooth until the beginning of this century. In it, too, until the Union, the Scottish Parliament and the Privy Council met. The "Laigh Parliament Hall"—the fine old room below the Parliament House—has been used for many purposes. Cromwell used it to confine his prisoners of war; in it the Covenanters were tried and tortured; part of it was used to preserve the Scottish records; and in 1700 the Town Council granted another portion to the Faculty of Advocates for their library, which now fills the whole and has overflowed into new buildings besides. But the town retained a portion of the Great Hall for its own purposes; for here, until 1798, the Bailie Court was held in one of the strange apartments into which the hall was divided. To the town fell the duty of maintaining the hall and court-rooms until this was taken over by the Crown in 1816. One municipal purpose the hall regularly served—it was used for public meetings called by the Corporation. Cockburn relates how the king's birthday banquet took place in it on June 4, and here many of the principal Edinburgh events were celebrated. As late as 1863 the Corporation banquet in honour of the marriage of the Prince of Wales was held in the old hall, which the city still claims as its property.

After the extension of 1632-39, the municipal buildings remained until the beginning of this century much the same as they were then made, save that the Corporation offices were all turned out of St. Giles's, except the town clerk's department in the north transept. But during this time a great change had come over the conditions of the country, for the Union of 1707 had changed all things in Scotland; the Crown had increased its power, and, unlike the old Stuart kings, could now afford to provide both salaries and house room for the College of Justice. A revolution came, too, after the second half of the century began, on the feelings of the citizens with regard to their places of abode. Of the need for a new council chamber there could be no doubt. The old room in the new Tolbooth is described by Lord Cockburn in his "Memorials," and the picture is not inviting. "It was a low, dark, blackguard-looking room, entering from a covered passage which connected the north-west corner of the Parliament Square with the Lawnmarket." "The chamber was a low-roofed room, very dark and very dirty, with some small dens off it for clerks."

The contemplated improvements, embracing as they did new court-rooms, a hall for the Society of Writers to the Signet, more accommodation for the Advocates' Library, a new prison, besides a town-house for the city, were extensive, and took many years to discuss before they were entered on. There were many parties to please, and among others the Treasury, which was not easy to bleed during the great French war. The beginning of the end of the old Tolbooth was intimated when the foundation-stone of the New Bridewell on the Calton Hill was laid in November 1791, the occupants of "The Thieves' Hole" being transferred to it on its completion. But the other residents in the old Tolbooth were allowed to remain for some years, for the Felons' Prison on the Calton Hill was not finished till September 1817. Then the old Tolbooth was rendered tenantless; the old door and padlock went to Abbotsford, while the cage or "Iron House" was bought by the town of Portobello as a "lock-up" house for that fashionable seaside resort. The old Tolbooth was pulled down. During the same period the new Tolbooth had met a

like fate. It had received warning as far back as 1790, when a plan was drawn up for improvements which included the clearing it away along with the other quaint old buildings, Goldsmiths' Hall, George Heriot's shop, and the closes which blocked the west front of St. Giles. But destruction showed that it had a "slow foot" in this case also, and the negotiations went on without result until 1809. Then the clearance of the space between the Cowgate and High Street from St. Giles's Church westward to Liberton's Wynd was finally agreed on, the new Tolbooth was also condemned, and the Town Council had to seek new quarters for itself. The fact is that for years the accommodation afforded by the new Tolbooth had been found much too narrow for the town's offices, and rooms had been taken in different parts of the High Street. Ever since the Reformation the town clerk had kept possession of the portion of the town's church in which he had then settled, and during the eighteenth century other departments found premises in one place and another. The most curious of these plantations is "The Burrow Room," to which the Dean devotes a short chapter. It was a room which the town held from 1701 to 1741 in one of the high tenements in the south-east corner of the Parliament Close. It was primarily used by the Convention of Royal Burghs, but it served other municipal purposes, and a very strange document is quoted in the Dean's sketch throwing very clear light on the character and habits of Captain John Porteous, who gives his name to the famous Porteous Mob.

The Town Council acted very sensibly in the emergency caused by the destruction of its chambers—it took possession of premises which had been in its hands for years, on the north side of the square, which is still called the Royal Exchange, and there it abides unto this day. How the Royal Exchange was built, and how the north side of its square fell into the hands of the Corporation, is fully told in the account now presented to the Town Council. It is a quaint story of the middle of the last century. It would appear that during the burst of enterprise which followed shortly after the suppression of the Rebellion of 1745, the Convention of Royal Burghs started a movement—intended to be national—for improving the capital of Scotland. Among other improvements it was resolved to build for Edinburgh an Exchange, in which her merchants could meet. Meetings were held, subscriptions collected and a site for the Exchange found on the north side of the High Street, by buying up Mary King's and Stewart's Closes, both of which were ruinous, and neither having a very good repute. Then, in 1753, an Act of Parliament was got, which authorised the scheme and appointed a board of thirty-three directors to control the undertaking, the directors being partly chosen from the subscribers of 5% and upwards, and partly from public bodies, the Town Council having a controlling voice in the matter. The cost of the scheme was about 31,500*l.*, and of this the Town Council was to advance 16,000*l.*, and to receive the north side of the square, which it had been arranged was to be taken over by the Government for a Custom House. Proceedings were commenced on September 13, 1753, by a great masonic and military spectacle, in laying the foundation-stone on the south-west corner of the square, the magistrates gracing the occasion in their velvet coats, as appointed for them by their "kind and gracious gossip," James VI. The building went on slowly, and splendid mason-work the old Exchange was really made. The square was completed, save that the old land in Writers' Court was allowed to remain. But the scheme was not a success financially. The buildings were sold as they were got ready, and the Town Council, although it had not been able to advance more than 4,100*l.* out of the 16,000*l.* promised, retained the side overlooking the Nor' Loch, and let it to Government for a Custom House at a rent of 360*l.* per annum. So the Royal Exchange remained for years, until in the beginning of the century the Government bought a new Custom House, and the Town Council needed council chambers, owing to the Tolbooths, old and new, being doomed to destruction. Quite naturally, the Town Council bethought itself of its property in the Exchange, and so after the matter had been carefully gone into by a committee, and a very clear and sensible memorandum drawn up on the subject, as much of the town property on the north side of the square as was required was fitted up for the Corporation business, and on May 14, 1811, the magistrates and Council took possession of their new place of abode. Here the town-house of Edinburgh still remains, but of late years the Corporation has very properly been steadily buying up the remainder of the square as it comes into the market. The Municipal Buildings require still further extension, and the Town Council seems to be taking the only sensible course in planning improved buildings in the Royal Exchange, rather than in seeking a new site elsewhere. A town like Edinburgh, which depends so much on its traditional importance, cannot afford to break the chain of its historical continuity by removing the home of its municipal life from the centre which it has known as long as its history can be traced to a new town and new surroundings.

BIRMINGHAM ARCHITECTURAL ASSOCIATION.

A PAPER was read at this Association on Friday evening, January 25, by Mr. Horace R. Appelbee, of London, entitled "Preparation of Drawings for the R.I.B.A. Prizes." Mr. Appelbee gave hints as to the best method of preparation, and suggestions on the order in which the various competitions should be taken, so that the study done for one competition might be of assistance in the following year if the student chose to compete for another of the prizes. Mr. Appelbee advised all students under the prescribed age to enter for the competitions, not only for the sake of the prizes, but because of the benefit derived from the necessary study. The paper was illustrated with drawings kindly lent for the occasion by Messrs. W. H. Bidlake, Arthur Bolton, George Kenyon, Frank Verity, and others. After the meeting Mr. A. G. Dunn was entertained at supper by a number of fellow-students of the Association and School of Art, to celebrate his success in gaining the Fugin Studentship.

SCHOOL BUILDINGS.

Blackburn.—In connection with St. Stephen's Mission Church a new, substantial and commodious infants' school has been opened to accommodate 270 scholars, with separate babies' room at one end. An improved glazed folding partition divides the two classes of infants. At the main entrance cloak-rooms and lavatories are provided, the inner walls being lined with white glazed bricks. A special feature has been provided in having the school well lighted, sufficiently heated by hot-water and ventilated on the most modern system. The school is built with Yorkshire parpoints and dressings. The cost, including furnishing, is upwards of 1,000*l.* The whole of the work has been ably carried out by Mr. T. P. Wilson, of Lower Darwen, and local sub-contractors, under the superintendence of the architect, Mr. J. A. Shorrocks, of 3 Simmons Street, Blackburn. Mr. Billington was clerk of works.

GENERAL.

Mr. Howard Pentland, architect, has been elected a constituent member of the Royal Hibernian Academy.

Messrs. Bailey & McConal, of Walsall, have been successful in the competition for the new swimming, Turkish and slipper baths, engine house and laundry, which are to be erected in Walsall at a cost of 7,500*l.*

The Designs by Mr. G. G. Hoskins have been adopted in a limited competition for the new schools to be erected in the parish of Holy Trinity, Darlington, and have received the approval of the Education Department.

A Meeting will be held at Assouan to-morrow between Mr. W. E. Garstin, Professor Sayce, Messrs. Naville, Farmer, Hall, Somers-Clarke, Hogarth and Lyons, to consider the best means of preserving the portion of the temples on the island of Philæ which will be partially submerged by the proposed waterworks.

Mr. Gleeson White will give an address at the meeting of the Applied Art Section of the Society of Arts on Tuesday, the 5th inst., on "Drawing for Process Reproduction," Mr. Lewis F. Day presiding.

Mr. C. H. Godfrey will read a paper at the meeting of the students of the Institution of Civil Engineers, on "The Construction and Maintenance of Roads."

The Surveyors' Institution meet on Monday, the 4th inst., when the adjourned discussion on the paper read by Mr. H. Blackburn on "The London Building Act, 1894," will be resumed.

Mr. J. T. Cackett will, at the meeting of the Northern Architectural Association in the Art Gallery, Newcastle-on-Tyne, give an address entitled "An Evening of Notes," with limelight lantern illustrations.

Mr. Percy Fitzgerald, F.S.A., will lecture on "Adam Architecture in London" at the meeting of the Edinburgh Architectural Association on Wednesday, the 6th inst.

Mr. G. B. Bulmer delivered a lecture on "Ancient Rome" to members of the Leeds Architectural Society. He described the venerable buildings, explaining their construction and good and bad points.

Whittington Church, of which Dr. Pegge, the Derbyshire antiquary, was for many years rector, has been completely destroyed by fire. The cause is supposed to be the overheating of a flue. The church possessed considerable historic interest, and the deeds, registers and plate therein were of great value.

A School of Architecture is proposed to be founded by the Turkish Government in Constantinople, in order to enable the natives to dispense with the Armenian architects.

The Leicester Town Council on Tuesday resolved to expend about 25,000*l.* on an art and technical school, which will be erected on a site belonging to the borough.

The Architect.

THE WEEK.

THE week was not favourable for builders in the law courts. On Monday application for leave to appeal brought by Messrs. GREGAR & Co. in a case where 200*l.* damages were awarded against them was refused. A foreman moved a plank, and a bricklayer who stood on it fell and was injured. The Court held that the mishap was caused by the foreman's act, and that there was ample evidence for the jury when the damages were awarded. On the same day Messrs. LYSAGHT & Co., of Bristol, were sued for 50*l.* damages. Their men were using some hoisting tackle for raising girders, and during dinner-hour a labourer who was employed in carrying planks was tripped by a wire rope and was seriously injured. The jury found for the plaintiff with 30*l.* damages. Mr. WILKINSON, a builder who had been carrying out alterations in a house at Bayswater, failed in his defence of an action brought by a lady. The coal-cellar, it was alleged, was utilised in connection with the work, and the plate being left insecure, the lady in slipping on it was injured. The builder contended that he was not liable, as he had in no way been negligent, and that the action had been brought against the wrong person. He denied that he or his servants had ever dealt with the iron plate which occasioned the accident. A special jury, however, found for the plaintiff, and awarded 85*l.* damages. On Tuesday an injunction was granted (but suspended for two months) by which Mr. BAILEY, a builder at Bushey Heath, was prohibited from using circular saws because they were declared to be a nuisance by a resident.

WHEN Mrs. THORNYCROFT, whose death occurred a week back, began to practise as a sculptor, there were fewer lady artists than in our time. But as the daughter of JOHN FRANCIS, who was one of CHANTREY's assistants, she must have become acquainted with clay and stone at a very early age. After her marriage with THOMAS THORNYCROFT she visited Rome, and became acquainted with JOHN GIBSON. It was through his recommendation Mrs. THORNYCROFT obtained the patronage of HER MAJESTY and the late PRINCE CONSORT, and idealised portraits of princes and princesses are the works with which her name is associated. Figures of four of the royal children as *The Seasons* were among the attractions of the Exhibition of 1851, and at the Paris Exhibition of 1855 the *Girl Skipping* found admiration on account of its technical excellence. Mrs. THORNYCROFT was no admirer of mere prettiness in sculpture, and owing to the scepticism which exists about the merits of works which are used for the adornment of an English palace, her power as an artist was not appreciated as it deserved. She was happy in being able to see that the ideal to which she aspired was realised in the works of one of her sons, Mr. HAMO THORNYCROFT, R.A.

On Friday last an interesting event took place in Edinburgh. The City Treasurer lodged 295,303*l.* with one of the banks in order to discharge so much of the debt on the city as had been incurred prior to 1833. In 1658 Edinburgh owed 54,761*l.* Forty years afterwards it had increased to 73,000*l.* In 1798 the debt exceeded 160,000*l.*, in 1817 the amount was 212,000*l.*, and in 1833 no less than 241,000*l.* In those days the Corporation was an *alma mater* in the fullest sense of the term. Religious instruction, education, the care of the poor were provided and paid for. Large sums were expended in building city churches. St. George's cost the city 38,626*l.*, exclusive of the site. The cost of the four New Town churches, St. George's, St. Andrew's, St. Mary's and St. Stephen's, including the value of the sites, and a sum of 7,626*l.* expended in the repair of St. Giles's Cathedral, amounted to 104,000*l.* That ecclesiastical property is still possessed by the Corporation. The improvement of Leith was also a burden on the city. The University and

High School should also be reckoned among the cares of the Corporation, although the expenses from their modesty would astonish the authorities of Oxford and Cambridge. For many years the college revenues were not sufficient to meet the expenditure, and had to be supplemented by payments out of the Corporation revenues. An investigation in 1835 revealed that the annual expenditure amounted to 2,093*l.* The college revenue, including the interest on a sum of 13,000*l.* lent to the city out of college mortifications, averaged about 865*l.*, leaving a deficiency of 1,200*l.* per annum to be provided by the Town Council. The salaries and expenses of the High School and other schools amounted to 400*l.* a year. An Act which was passed last year has enabled the Corporation to make financial arrangements by which the debt of the city will be reduced by 295,000*l.* The benefit to the ratepayers will be only about $\frac{1}{2}$ *d.* per pound, but Edinburgh is "relieved from an undignified position with regard to a part of her property and revenues," and the keeping of the municipal accounts will become a simpler task.

THE seventeenth annual general meeting of the members of the Royal Scottish Society of Painters in Water-Colours has been held in Glasgow. The annual report stated that the exhibition in November was the most successful exhibition, financially and otherwise, ever held by the Society. The statement of accounts showed the income to be 430*l.* 13*s.* 11*d.*, and the expenditure 382*l.* 15*s.* 5*d.*, leaving a balance at the credit of revenue account of 47*l.* 18*s.* 6*d.* Balance at the credit of capital account now amounts to 888*l.* 13*s.* 7*d.*, an increase of 89*l.* 18*s.* 6*d.* during the year. The following officers were elected:—President, Sir FRANCIS POWELL; vice-president, W. M'TAGGART, R.S.A.; treasurer, A. K. BROWN, A.R.S.A.; auditors, W. YOUNG, R.S.W., and GROSVENOR THOMAS, R.S.W.; members of Council, R. M. G. COVENTRY and WELLWOOD RATTRAY representing the west, and JOHN MUIRHEAD and ROBERT ALEXANDER representing the east of Scotland.

THE position of architects when "Ireland has her own again" may be anticipated from an action which was brought on appeal before the Queen's Bench Division in Dublin on Monday. Mr. THOMAS BERRY prepared plans for labourers' cottages, and did other work in connection with the Act by which money is granted for those most needed of structures. His services extended over several years. The employers were the Guardians of the Shillelagh Union, a name that must inspire terror in all men who have frangible skulls. When the bill, which amounted to 314*l.*, was sent in, they refused to pay it, and when brought before the Courts they contended, in a characteristic way, that it was within their rights to dismiss an architect whenever they pleased and withhold all his remuneration. However, they lodged 90*l.* out of deference to English law, and, we suppose, congratulated themselves that a good time was coming when equity of another class would prevail. The claim was assigned to the consideration of one of the masters, who allowed 78*l.* in addition. Mr. BERRY will therefore receive a little over a half of the sum he earned, and we suppose creditors of the well-armed people of Shillelagh would say he ought to consider himself to be unusually lucky.

THE Spring Exhibition of works in black and white and water-colours will be held in the Walker Art Gallery, Liverpool, during March, April and May. There will be a special room for architectural drawings which will be arranged by Professor SIMPSON, the principal of the School of Architecture and Applied Art. The limit of wall space in the room allowed to each exhibitor will be 30 square feet. The following are admissible:—Drawings to scale, plans, elevations, sections, &c., mounted on strainers; drawings to scale, framed and glazed; perspectives, if accompanied by plan or plans, either on strainers or framed and glazed; photographs of executed work, if accompanied by plan or plans; measured drawings or sketches of old work, mounted on strainers. All works are to be delivered not later than the 20th inst.

WHAT IS ART?

THE claim to have acting "classified officially among the fine arts," which Mr. HENRY IRVING advocated at the Royal Institution, may have compelled some among the auditory to ask themselves what is art, and how are the fine arts differentiated from the useful arts and the dramatic art? If so, the querists must soon have discovered that a reply was not readily forthcoming. Probably to no men are the questions more puzzling than to artists and those who possess familiarity with the theory and history if not with the practice of the arts. The late Sir DIGBY WYATT came the nearest to mastership of the arts of all men in England during the present century, yet when he was called upon to answer them, with all his ability and experience he shirked the duty. In his introductory lecture as the first SLADE Professor at Cambridge, he said:—"In attempting to answer the question of 'What is fine art?' it would be unwise and unprofitable to lead you into any metaphysical fogs; and it is preferable to seek a solution of the question in the observation of man's practice, rather than in an investigation of his perceptions and intellectual affinities." Where Sir DIGBY WYATT feared to tread it is, of course, hazardous for a weaker man to enter. But as long as metaphysical fogs prevail, it is perhaps allowable that unexpected claims for recognition as artists should be uttered by men who used to be known by different titles, like the needy tailor who lately startled the Chief Justice by describing himself on oath as "an artist in cloth."

Mr. IRVING can therefore claim excuse for any lack of precision which may be found in his definition of fine art, or in his ideas of the advantages which would arise to himself and his brethren by any formal and official recognition. It is evident that, like Sir DIGBY WYATT, he prefers to seek solutions of the questions in men's practice. According to Mr. IRVING, acting is part of human nature, and is the method of education established by nature; like the recognised fine arts, it implies a knowledge of the powers of nature, and the systematisation of them in such a way that effects might be recurrent as required. Whatever was essential to poetry, music, sculpture and painting was also essential to acting, and it seemed irrational that HOGARTH's *David Garrick as Richard III.* should be accepted as a work of art, while to GARRICK's interpretation of the character that title was denied.

We suppose Mr. IRVING will allow that GARRICK was indifferent to the distinction which is now coveted. He looked on himself as a greater man than HOGARTH, and as superior to his old tutor, SAMUEL JOHNSON. If it had been proposed that GARRICK was to be attached to the Royal Academy as professor of posing and grouping he would probably feel aggrieved. A man who was able to look forward to a funeral in Westminster Abbey, surrounded with all the pomp the art of the undertaker could devise (there were six black horses to each coach, says the chronicle), was not likely to covet association with the notabilities of St. Martin's Lane any more than with the notabilities of Grub Street. Both classes of men were eager to flatter him, or as GOLDSMITH said, to be-ROSCIUS him. The arts in those days were not much esteemed, and we are inclined to doubt whether, if they were now as then, Mr. IRVING would be ambitious to be classed officially with their representatives. The great question, however, is, Would GARRICK have been a better actor if some official stamp were placed upon him or his name entered in a record of some circumlocution office? Was it not worthier to be represented with his arm round SHAKESPEARE's bust as if he were the guardian of the dramas, and to expect that one day "Old SHAKESPEARE would receive him with praise and with love"?

The question still remains to be answered why a picture may be more important than its subject, or how a painting of a cabbage may attain the value of many acres of cabbages. We must esteem, in the first place, the victory which the arts of painting and sculpture gain over time. Vegetables and actors, like other living things, are doomed to vanish; art furnishes a substitute for them, although the artist himself must share the common doom. The actor, it is true, holds the mirror up to nature, and, it may be, more faithfully than any painter, but the representation is only evanescent.

According to contemporary accounts GARRICK's attempt to realise King RICHARD was very impressive. Unfortunately, it cannot be recalled. The traditions of his interpretation are so vague as to be valueless, for no actor or professor of elocution would venture to say how he expressed the terror of the tent scene; while HOGARTH, on the other hand, has recorded one of his attitudes, and with the aid of fate and reproductive processes that attitude has gained immortality. Other painters and engravers have preserved for us his appearance in different scenes, and copies have gone the round of the world. But the voice that was so varied, natural and affecting is for ever dumb. There is the real pathos, the tragedy of the actor's life, the true paradox of the comedian. The booth outlasts him. SCHILLER, in that noblest of all prologues, excites sympathy by the contrast between the player and his surroundings. The old Weimar theatre had been furbished up for "Wallenstein," or, as he said, it had rejuvenated itself, and was destined to witness the triumphs of many young performers, as it had in past years. But of the wonderful art of which it was the temple no trace was to remain, no crown of immortality awaited the actor; the magic was only for a moment. As poor ADRIENNE LECOUVREUR is made to say by SCRIBE, "Rien ne survit à nos autres—rien que le souvenir." That souvenir has been preserved by art and literature. IFFLAND will always appear to lovers of SCHILLER as "ein edler Meister," unless they read the actor's sentimental dramas. ADRIENNE continues to be pitied, and GARRICK remains the glory of the English stage. But how was death conquered? Mr. IRVING would say through the merits of the performers. Is not ROSCIUS, he asks, a name that lives in history, though he was neither poet, nor sculptor, nor painter, nor architect, nor musician? He forgets that the comic actor owes his fame to an oration of CICERO. There must have been more of the antique Roman in ÆSOPUS, but as he was connected with no big financial case, he is as a phantom to us. On how many actors has one essay of CHARLES LAMB conferred immortality? JACK BANNISTER, MUNDEN and ELLISTON found other eulogists, but without ELIA who in our time would recall BENSLEY, DICKY SUETT, DODD, KING, the PALMERS and the rest? Who can now forget them?

Mr. IRVING made merry over the works of the artists among whom there is no formal and official recognition of actors. He asked in his most withering tone:—"Where is the mighty city Babylon, with its walls and temples and gardens?—gone. Where is the mighty statue of *Olympian Fove*, the triumph of PHIDIAS?—gone. Where is the Temple of Diana?—gone. Where is the Mausoleum of Artemesia?—gone. Where is the Pharos of Alexandria?—gone. Where is the Colossus of Rhodes?—gone. Ay, and gone with them millions of art works by myriads of workers in countless ages—men now nameless, but once full of honour, and whose work was and is placed in the existing category of the arts." That is the inevitable law, but if the works he mentions are now in exactly the same position as the art of the actors who have made their exits, they at least survived for ages, and for that we ought to be thankful. Where all the odds are against us, the smallest gains are welcome.

The truth is Mr. IRVING put the actor's art on its worst basis when he attempted to compare it with works in stone or bronze, on canvas or paper. They are records of men's power enduring for a time if not for all time. We might say the artists who produced them, like the authors of books, were actors, who were not compelled, like those who trod the stage, to be avaricious of the present, as there was no future for them. REYNOLDS advised the Academy students to imagine they were MICHEL ANGELOS and RAPHAELS when about to treat a pictorial subject, "as if the tragedy were played in jest by counterfeiting actors," and that sort of simple histrionics, the putting oneself in the place of some supposititious man, is common enough in all the artists. It was a facility which M. TAINE found to prevail more generally among young artists than any other. But there is something more than applause as the record of so fine a frenzy, for by its means works of art are produced. The painter, the sculptor, the architect, even the musician, can create. Their works are not baseless fabrics which dissolve like a dream, while the glorious creations of the actor are as unsubstantial as PROSPERO's pageant,

"cloud weavings of phantasmal hopes and fears." When there is so vast a difference between the results of their art and those of other men, how can actors expect to be classified officially with painters, sculptors and architects?

When he says that a sculptor's talent can be as well exhibited in modelling a piece of butter as with harder materials, Mr. IRVING we fear will make the judicious grieve. If sculpture were produced only in stuff that was easily dissolved, the art would be in the same category as acting. Men would grow weary of the failure of their endeavours to preserve the creations. They treasure wax models by great artists on account of their rarity, and the care that had to be taken to keep things so frail from succumbing to time; the models also have the advantage of being the genuine, the unaided works of their authors; but a sculptor who insisted on abandoning the use of all materials except wax would soon discover his patrons were only to be found among the showmen. Ours is a material world, and the arts like most mundane things must be subservient to the omnipotent principle of property—

Proputty, proputty's ivrything 'ere, an' Sammy, I'm blest
If it isn't the saäme oop yonder, fur them as 'as its the best.

When the art of the tragedian or comedian has attained a money value in CHRISTIE'S rooms, it will be time enough to hanker after official classification.

But if their art is not embodied in a form that can be assessed for probate and other duties, the actors have compensations enough. They have the exalted privilege to be the interpreters of dramatists, and, as there can never be any official classification for those mysterious or miserable beings, how can actors expect a different fate to their inspirers? They should remember, also, how limited is the scope of all the official fine arts. The majority of those arts can only gratify the eye. But the actor, with the aid of the writer, can sway men's feelings and intellects. To anyone who saw GARRICK as RICHARD III., HOGARTH'S picture must have been as cold and disappointing as MACLISE'S *Macready as Werner* now appears to all who can recall the old master in his declining days, when he played to empty benches, manfully struggling against himself to discharge a duty and conquer the weariness of life. No painter's work can express a tithe of the sadness which MACREADY imposed on all who saw him in that character. On such occasions, the actor who has the genuine gift becomes a magician. Then it is, as JULES JANIN finely said, "Est deus in nobis"—each of the spectators is the god who kills or who saves, who holds the sceptre or the thunderbolt, each submits to the great art, because it has its principle in the soul and touches whatever is in the heart of man, however deeply concealed. At such a time how powerless is painting or sculpture! If to represent the two brothers who ruled in Denmark portraits by RAPHAEL and TITIAN were hung on the canvas wall, would the scene between the son and the mother become more terrible? If a genuine polychrome statue by "GIULIO ROMANO" were placed in the niche in PAULINA'S house, would anyone care to see the remorse of LEONTES before it? Or, to leave imaginary cases, can we believe that the *Polyeucte*, when seen lately in the great Roman theatre at Orange, moved spectators more than when played in the Théâtre Français? Painting, sculpture and architecture must hide their diminished heads before the Tragic Muse, yet knowing this we see one of her priests forgetful of her importance, and craving to be "classified officially among the representatives of the fine arts." If MELPOMENE forgives him she also has become one of the decadents of the end of the century.

NOYON CATHEDRAL.

THE importance of Noyon Cathedral in the history of Gothic architecture was suggested by DE CAUMONT nearly sixty years ago, when he described it as an excellent example of the Transition style belonging to a time when Gothic architects made use of forms and accessories which were Romanesque. No less emphatic is FERGUSSON'S judgment, and what he says is the more remarkable because of his bias against Gothic:—"The cathedral of Noyon is one of the best and most elegant Transition specimens in France, having been commenced about the year 1137, and

completed as we now see it in 1167. Here the circular arch had not entirely disappeared, which was owing to its early date, and to its situation near the German border and its connection with the see of Tournai, with which it was long united. Like the sister church of that place, it was triapsal, which gave it great elegance of arrangement." There is, we need hardly say, a difference between the two buildings (which are ninety miles apart) in the position of the apses. The choir or chancel at Tournai is almost double the length of the Noyon choir, and as the apsidal ends of the transepts are so far from the chancel apse their relation is likely to be overlooked at Tournai, whilst at Noyon it becomes evident from a cursory glance. There is no less important a difference in the manner of constructing the apses, which M. CORROYER describes as follows:—

In France we shall find no example more deeply interesting than Noyon, which at the date of its construction (the last quarter of the twelfth century) formed, as it were, an epitome of the advance so far made by the architects of the Ile de France. In this curious building we find a fusion of the antique tradition developed by the Normans in their triforiums, and of the Angevin methods, as manifested in the groined vaults derived from domes; methods further protected by the example of La Ste Trinité at Angers; in other words, by the adoption of intersecting arches planned on a square, the thrusts of all being received on the main piers, reinforced by an intermediate transverse arch. And we note the appearance of the detached semi-arch beneath the roofing of the inferior aisles merging at its springing into the lateral *arc doubleau*, and so resisting the thrust of the intersecting arches and transverse arches of the nave. It has been said that Noyon was suggested by Tournai, doubtless on account of their superficial affinities. But the likeness is merely in general aspect, the methods of construction being wholly different. At Tournai the apsidal transepts are vaulted upon transverse arches of great strength, and upon radiating semi-arches united where they meet by a ring of voussoirs set horizontally, and at their springing by vaults keyed into their mass, an ingenious arrangement which recalls the vaulting of the "Salle des Capitaines" over the porch of the monastery church at Moissac. At Noyon we have groined vaults, the intersecting arches of which demand the reinforcement of abutments either concealed or apparent, to sustain the thrust of these vaults over the lateral *arcs doubleaux*.

Although the building possesses so much interest as an example of construction, it is less known to students of architecture outside of France than it merits. Noyon suffers from its position. Amiens, Laon, Coucy, Beauvais and Rheims, which form a sort of circumference for the circle of which it is the centre, are held to be more attractive, and by most strangers are first visited. Noyon is left over and then it is found there is no time for the study of the building. The exterior of the cathedral is rather sombre, and the two towers are suggestive of defence. The prelates were sometimes of a militant class, and at Noyon they possessed the power of feudal lords. The arching of the windows does not suggest the buoyancy which those of a later period generally inspire. The porch is vast, and appears to be adapted for ceremonies no less than for sheltering a crowd. The first sight of the interior is impressive. The piers and arching are rigorous in their plainness, and the sculptured ornament is generally strictly conventional, but the proportion of the parts is satisfactory, and there is an expression of repose about the nave which can hardly be disturbed by glimpses of chapels with the tawdry decoration which pious people admire. The alternation of square with cylindrical piers does not appear discordant, but rather as an effort to secure quietness of effect. What appears surprising is that, unlike the majority of buildings, the progress of development is not easily to be traced as we ascend. The lower arcades have more analogy to pointed arches than those which are found at a higher level. It is not easy to understand how the peculiarity has arisen, unless we imagine that we see in the round arches the work of a time of which they were not the characteristic. Is there any evidence to support the theory that the builders of Noyon, like those of our day, sacrificed the present to the past?

As a city Noyon resembled those people who are not born for good luck. It might have given its name to a special variety of misfortunes, for it was not only left defenceless to invaders, but it was periodically subjected to fires which arose within its own buildings. If it were argued that the gloomy views of life which were always before the most distinguished of the citizens, JEAN CAUVIN, were the consequences of belonging to a family that had suffered much in Noyon, believers in heredity and the

influence of exterior circumstances on thoughts would be likely to agree with the conclusions. The earliest bishop of the see who was a historic character was Saint MEDARD, who lived in the early part of the sixth century, and he gained his fame by his efforts to save his flock in Noyon from the onslaughts of barbarians. Saint ELOI, who was one of the bishops in the next century, was a famous metal-worker and professor of art. He was, moreover, prime minister to DAGOBERT, but, however busy, he was compelled to spend a part of his time in trying to raise money in order to free slaves from captivity, and the last circumstance suggests the risks which awaited residents in Noyon. In the ninth century Bishop IMMON was among the victims who were massacred during one of the invasions of the Normans. We hear of elections of bishops by the people and of other bishops they opposed. So constant were the quarrels between the inhabitants and the cathedral authorities, it was a stereotyped entry in the capitular records that peace had been again entered into between them, "*de pace facta inter nos et burgenses Noviomenses*," and the number of entries about a truce is evidence that peace was not enduring. In 1108 Bishop BAUDRY granted a sort of charter to the townspeople. A few years afterwards there was a tumultuous conspiracy on their part, "*turbulenta conjuratio factæ communionis*," to coerce one of his successors to accept their interpretation of the conditions.

The fires were numerous in Noyon, and the cathedral was sure to suffer. In 1131 the building was destroyed. In consequence of that catastrophe the see was separated from Tournai. Twenty years afterwards there was another fire. A new building was commenced in the episcopacy of BALDWIN II., who was a friend of Saint BERNARD, and would as such believe in the necessity of severity in churches. The building was completed in the time of STEPHEN I. In 1293 there was another fire, when nearly all the churches of Noyon were destroyed. During the sixteenth century there were three conflagrations, the last being on the occasion when the Spaniards attacked Noyon, which was valiantly defended by a band of Scotsmen, but they were overcome by numbers. All the canons had abandoned the cathedral. Apparently some of the inhabitants believed it was sacred and fled to it as a sanctuary, but there was slaughter within it, and it had to be purified when the canons returned.

It may be assumed that no part of the building can be of an earlier date than 1151, and it is doubtful whether any important part was erected at a much later period. The fires after the twelfth century, which appear so terrible on the records, cannot have caused much injury to the building. If there was rebuilding the customary practice was not observed, for in Noyon there is no variety of styles. With the exception of some of the side chapels the building may be described as representing no more than two styles; it would be more correct to say it consists of two phases of a Transitional style, and that the later first appeared. It is held that the notion of motion should be excluded from geometry, and that it is unworthy to imagine that a geometrical line is formed by the revolution of a geometrical point. It is considered also that we must not think of contests in connection with masses of masonry. But at Noyon it might be supposed that the tendency towards thirteenth-century lightness was arrested; columns and arches consequently show opposing influences, and finally the newer fashion was compelled to succumb to the more ancient. If we could believe that the new designers were laymen while the elders were clerics, the peculiarity of Noyon would be explained. As we have seen, it was a place where conflicts were known. The civilians and the canons were in opposition, while on the bishop, as a sort of combination of spiritual and secular power, devolved the troublesome office of arbitration. Does not the architecture of the cathedral suggest compromise as well as contests? There are parts of the building which in other districts of France at the end of the twelfth century would be considered as obsolete in style, and it is plain that the men who designed the work were aware it was obsolete, but they submitted to some power which could control them.

The apses of the transepts are examples. Possibly in the more ancient cathedral of Noyon that arrangement

existed, while some suppose it was retained out of affection for Tournai. It is evident, however, there was no symbolic or ritualistic advantage in making the transepts end in a semicircle, for otherwise the examples would not be so few in France. When we find marked peculiarities of that sort we are justified in supposing that some exceptional influence held sway, and for that reason we consider that the cathedral of Noyon has an interest which is absent from later, and it may be more beautiful, examples of French Gothic.

YORKSHIRE ARCHÆOLOGICAL SOCIETY.

THE thirteenth annual meeting of the members of the Yorkshire Archæological Society was held on January 31, at the Town Hall, Leeds. Colonel Wilson presided. The following is the annual report:—

The Council of the Yorkshire Archæological Society, in presenting their thirtieth annual report, feel that much good work has been done during the past year, which has seen the issue of the fiftieth part of the Journal. The Council look upon this with legitimate pride, and feel sure the volumes will be an invaluable help to all students of Yorkshire antiquities. In the forthcoming part will be commenced a new translation of Domesday Book for Yorkshire, which will be accompanied by copious indices of persons and places—a work which cannot fail to be of great use. During the past year a new departure was made in having a two days' excursion to York. This experiment proved eminently successful, and the thanks of the members are due to the Right Honourable the Lord Mayor, the Hon. and Very Rev. the Dean of York, F.S.A., the Rev. Chancellor Raine, D.C.L., and the Town Clerk, as also to Mr. W. H. St. John Hope, Mr. J. T. Micklethwaite, F.S.A., and Mr. John Bilson, F.S.A., for their lucid explanations of York architecture and glass. The Council of the Royal Archæological Institute propose to make Scarborough their centre for excursions in the present year. Your Council have been invited to join them, and it has been decided to accept the invitation. In the list of additions to the library will be noticed the important gift by the Harleian Society of forty-five volumes of their publications. The library is also increasing daily by the addition of the volumes received in exchange from the corresponding societies. This, and the rapid growth of the Society generally, render it imperative that steps should be taken to obtain rooms in some central position in Leeds, where the library could be housed and meetings held. During the year 37 new members have been elected into the Society, which now numbers 4 honorary members, 177 life members, 428 annual members and 27 corresponding societies—a total membership of 636. With regard to the Record series, only one volume has been issued during the year, namely, Volume XVI., containing the Yorkshire portion of the Lay Subsidy, collected 25 Edward I. This volume has been edited by Mr. W. Brown, who has another volume of Yorkshire Lay Subsidies in hand for the Society. Mr. Brown is also preparing another volume of inquisitions for publication, and it will probably form one of the volumes for the year 1897. The next volume of Lay Subsidies will, it is hoped, be issued in 1896. The second volume for 1894, Mr. Baildon's volume of notes relating to Yorkshire monasteries, is nearly ready for issue. It was hoped that this volume would have been in the hands of subscribers some months ago, but unexpected and unavoidable delays have arisen, for which the indulgence of subscribers is asked. The volumes for 1895 are now in hand. They will be (1) a further instalment of the "Index of York Wills," which has been prepared by Mr. A. Gibbons, and will be edited by Dr. Collins; and (2) a further instalment of the "Royalist Composition Papers for Yorkshire," which will be edited by Mr. J. W. Clay. It is hoped that both of these volumes will be in the hands of subscribers before the end of the year. It will be seen from the balance-sheet that the York Wills Fund is now nearly exhausted. After paying for the volume of index, now being prepared by Mr. Gibbons, and for the alphabetical arrangement of the volumes, the balance in hand will be very small. Further subscriptions, therefore, are needed in order to carry the index up to the year 1636, as suggested in the report for 1893. The number of subscribers to this series does not increase, and the average number (about 170) is far less than was expected when this branch of the Society's work was instituted. It was then confidently hoped that 250 subscribers would be obtained without difficulty, but this hope has not yet been realised. If all the patrons and all the members of the Council would become subscribers, there would be a substantial increase in the number. At present the subscriptions barely pay the cost of printing and postages, and therefore there is no fund available for copying purposes. The Society, therefore, is dependent on the kindness of friends for the preparation of the volumes issued to subscribers, and if, unfortunately, these friends should

happen to fail us, the publications of this series will have to be considerably reduced.

The Chairman, in moving the adoption of the report and balance-sheet, referred to the item for printing in the latter. It might seem a large sum of money, 223/, but he had no doubt they were all well pleased with the Journal. They would all be glad to see the appearance of what he might call a translation of the Domesday Book, which had been before the public for many years, but was not in as complete, accurate and intelligible a form as the new edition would be when finished. With regard to the Record series, the balance-sheet showed that the special subscriptions for indexing the wills at York were very nearly exhausted. He believed that every one would be glad to see those wills approaching completion. Colonel Wilson, referring to the suggestion in the report that they should have a room in which to house their books, &c., said he had felt for a long time that this was a necessary step to take if they were to expect the Society to progress even at the same rate it had hitherto done. So long as they had a library stowed away in a more or less inaccessible spot, and had no place which they could call their home, they were to a certain extent an outcast Society. If the Thoresby and kindred societies could be induced to share the expense of the enterprise, it might perhaps be brought within the limits of their somewhat slender means. If they had a home, they might be able to look forward to the gift of objects of interest. They were now possessed of a library, but beyond books they had little, if anything, of interest relating to the county. There were any number of engravings and maps, which would be of interest; even Roman altars were dug up now and then, like the one from the bed of the river at Castleford, which, he was glad to say, was now safely housed in the Philosophical Hall at Leeds. He felt that if they could only provide a place for their books, and in which they could hold their meetings, they would be in a position to invite the generous to make them gifts. The Council, he added, would be glad to have an expression of opinion on the subject, and he hoped before long that they would have a tangible scheme to place before them.

The following members of the Council were re-elected:—The Rev. J. T. Fowler, F.S.A.; the Rev. Canon Isaac Taylor, LL.D.; Lord Hawkesbury, F.S.A.; Mr. W. P. Baildon, F.S.A.; Colonel Wilson, F.S.A.; Dr. Leadman, F.S.A.; Dr. Carter Mitchell, F.S.A., and Mr. John Stansfeld.

HERALDRY.

ON last Saturday Mr. Robin Allen delivered a lecture at Toynbee Hall on Heraldry. Historical records, he stated, afforded no clue to the earliest devices in the shape of family pennants and coats-of-arms, but there was little doubt that the plumes and other symbols used by knights and feudal chiefs, to enable their followers to rally to their respective standards, had led to their subsequent adoption in the shape in which they had been handed down to posterity by the mail-clad warriors of earlier times. There was, however, much that was at least singular in the way in which some well-known and classic symbols had originated. What afterwards became the Roman eagle was originally a wolf, and the eagle did not supplant this ancient symbol until the consulate of Marius. During the Middle Ages heralds were appointed by monarchs and were known by their heraldic names, the higher titles such as kings-at-arms being conferred as rewards of merit and long service. These kings-at-arms were charged with the registration of the arms assumed by the nobility and chivalry of their day, and they also had power to award military honours and to decree the punishment of unknighly deeds. The impetus given to the religious and martial spirit of European chivalry by the Crusades had a good deal to do with the way in which the machinery of feudal warfare was methodised, and with the modes adopted of distinguishing and defining the followers of the leading warriors. To keep the men belonging to the respective chiefs together they had to be badged, and these badges were of a character embodying the personal symbols of the different knights. When the same sort of ornaments or symbols were selected by more than one chief, it became necessary to vary their appearance by alterations both in form and colour, which probably accounted for the blue boars and red lions so often heard of. The tints affected by heraldry were blue, red, green, black and purple, and the two metals which were distinguished from the heraldic colours were or (or gold) and argent (or silver). To these furs were added—ermine and vair, the latter being an imitation of the peculiarly marked throat of the northern squirrel. A peculiar feature resorted to in the use of armorial bearings was the adoption of supporters by which the knightly shield was upheld or guarded. Some of the early English monarchs had griffins and eagles, then a leopard and a unicorn, until at last a national symbol, which existed to the present day, was found in the lion and unicorn. Flags and banners of all kinds were of very ancient service, and their

adoption in the Royal and mercantile marine was of the greatest importance. The lecturer concluded by explaining how the Union Jack of Great Britain and Ireland was a combination of the three crosses of St. George, St. Patrick and St. Andrew, and by also describing the national flags of the chief countries of Europe.

ARMENIAN ARCHÆOLOGY.

A CORRESPONDENT sends to the *Manchester Guardian* the following interesting communication:—

At the present time, when the condition of the Armenian subjects of the Porte is exciting so much attention, it may be of interest to ascertain a few facts as to the ancient history and archæology of the Armenian kingdom. Few persons are aware of the existence of any Armenian history beyond the worthless jumble of ecclesiastical and late Greek tradition contained in the chronicle of Moses of Khorene, and the fact that ancient records of the kings of Armenia exist as far back as the middle of the ninth century before the Christian era is known only to those who have studied the more recent results of Assyriological research. The existence of rock and other inscriptions in the provinces of Central Asiatic Turkey was first noticed by the French traveller Saint Martin in 1823, and the first step in exploration was taken in 1826, when the French Government despatched Professor Schultz on a mission to study the archæology of the district and to copy inscriptions. The results of the expedition were unexpectedly rich, for Schultz copied more than forty inscriptions; but unfortunately the brilliant *savant* lost his life in the work, being assassinated on the Persian frontier in 1829. From time to time travellers in the regions of the head waters of the Tigris and Euphrates continued to bring home copies of fresh inscriptions, and in 1850 Sir Henry Layard spent some months in the region, and copied a large number of the rock and other inscriptions. It was then ascertained that over a large area, extending from Malatiah, on the Upper Euphrates, to the neighbourhood of Hassan Kaleh and Toprak Kaleh, near Erzeroum, and as far south as the Keli-sheri Pass, near Mount Rowandiz, in Western Persia, there were records written in a cuneiform character which was not that of the Assyrian empire or of the later Persian monarchs. The inscriptions presented a strong resemblance to those which Layard had found at Nimrud, and which were the records of the kings of the Middle Assyrian empire, extending from B.C. 900 to 750, there being only some slight palæographical variations. It was this close resemblance which led Dr. Hincks in 1847 to attempt the work of decipherment, and he succeeded in reading the names of most of the kings and of many of the place names recorded in the texts. Little progress was attained, as the language of the inscriptions, when deciphered, presented a tongue to which no existing analogue was known. Lenormant, who neglected no branch of cuneiform literature, and with the ardour of a Frenchman rushed in where others feared to tread, published an elaborate analysis of the inscriptions in 1871, and suggested their connection with the pre-Aryan or Alarodian tongues of Western Asia, now represented by the Georgian and especially the dialect of the Laz tribes near Batoum. The progress of decipherment was much hampered by the idea, prevalent in the minds of Mordtmann and others, that the language of the inscriptions was in some way related to the present Armenian tongue, which is a distinctly Aryan language. In 1880 the brilliant but ill-fated M. Stanislas Guyard, a pundit in Oriental languages, made an important discovery. Already having noticed the close analogy there was in arrangement between the Vannic inscriptions and those of the kings of the Middle Assyrian empire, he proceeded to analyse the groups, and was able to decipher a considerable portion of the shorter inscriptions. He was followed shortly after by Professor Sayce, who published translations of the greater number of the inscriptions in the *Journal of the Royal Asiatic Society* in 1882.

The conjecture of Lenormant was found to be in the main correct, that the inscriptions were in a dialect presenting some, though not many, affinities with the Georgian. The story revealed by the inscriptions is a remarkable one, and is, indeed, almost without a parallel in Oriental history. The district, which may be roughly described as the vilayets of Van and Diarbekir, lying between the shores of the lake of the former name and the head waters of the Euphrates, was known to the Assyrians as the land of Uradhu or Ararat, and was first invaded by the Assyrian armies under Dayan Assur, the tartan or commander of the armies of Shalmaneser II., in B.C. 833, who defeated Seduri, king of Ararat. This monarch is evidently the Sar-duris whose inscription is found built into the wall of a ruined church at Van. This inscription reveals a remarkable fact. It is not written in the Vannic tongue, but in Assyrian, and the king calls himself "king of the land of the Nairi," another name for this region of the head waters of the Tigris and Euphrates, which in turn is replaced by the name

of Baina in the native inscriptions of later kings. The text of the tablet is an exact copy of the formulæ of the inscriptions of the Assyrian kings Shalmanesar and Assurnazirpal. The interesting discovery then revealed to us is that the Assyrians who conquered Armenia in B.C. 833 placed, as we know, tablets recording their victories upon the rocks, and that the Vannic rulers were anxious to have the same records, but apparently had no writing of their own. In order to gratify their desire, therefore, they employed Assyrian scribes to write the inscriptions in the same style as those of their masters. In the next reign, however, that of Ispuinis, the scribes had succeeded in adapting the Assyrian notation to the native tongue, and in that language they were inscribed for the benefit of future generations. The process of borrowing was a most remarkable one; not only were the simple characters of the Assyrian selected, but whole groups of ideograms also, representing such common words or phrases as "horse," "chariot," "cattle," &c., and it was the occurrence of these with the variants occasionally given which rendered the process of decipherment more simple. The period covered by the inscriptions is a most important one, embracing about ninety years (B.C. 833-743), during which, owing to the weakness of Assyria, our knowledge of Western Asiatic history is extremely meagre. The continuous wars of Assurnazirpal and his son, Shalmanesar II., had restored the Assyrian empire to its former greatness, and the whole of Western Asia was subject to their power. As is the case with most Oriental empires, a period of weakness soon followed, on which Assyrian history, which never records reverses, is silent.

It is this period that is filled by the records of the Vannic kings. The ancient name of the kingdom was Baiana, which has been corrupted into Van, but the capital seems to have had the name of Dhuspas, which still survives in the modern Thosp, now the name of the district around Van. The inscriptions present no indications of a literary style, being little more than the enumeration of the amount of booty taken in the raids of the Vannic armies. These raids, however, are not without interest, for they show the existence of two important States in Western Asia—the Hittites and the kingdom of Milid, the modern Malatiah. Both of these kingdoms attained to considerable power during the ninth century before our era, and remained formidable until B.C. 717, when they were reduced to the position of Assyrian satrapies. In the reign of Argistes, which may be placed about B.C. 770, the Vannic kingdom was sufficiently strong to attack Assyria and to inflict a defeat on the armies of Assur. In his inscription the king says, "To the Khaldesis [gods of Van] I prayed, to the supreme powers who had given the armies of Assyria as a present to the race of Argistes." On the revival of Assyria the power of Armenia declined, and in B.C. 708, at the latter end of the reign of Sargon, the country was reduced to the position of an Assyrian province. The most remarkable feature of the campaigns recorded in the inscriptions is the fact that they are just such raids as are now and have from all time disturbed the country. Thousands of sheep, oxen and horses are carried off and men and women slain, and even outrages such as are now mentioned are recorded in the inscriptions. Three events combined to bring about the overthrow of the Armenian kingdom, first, the invasion of the Gimmerians, or Kimmerioi, in B.C. 680; then the gradual westward drifting of the Aryans, first the Medes and later the Persians. It is, however, very important to notice the prominent part that this little-known kingdom played in their influence upon the conquerors. Just as it was the setting up of inscribed records on the rocks by the Assyrians which led the kings of Van to adopt the cuneiform mode of writing, so it seems that it was the sight of the numerous rock inscriptions of the Vannic kings Menuas and Argistes that induced the Persian kings to set up their rock tablets. On the rock citadel of Van, by the side of the inscriptions of Argistes, is a tablet bearing a long inscription of Xerxes, but which, the king tells us, was originally prepared for his father, Darius. In another and even more important manner the Armenians exercised a great influence upon their Aryan conquerors. One of the greatest puzzles of Oriental archæology has been the exact connection between Persian art as represented by the sculptures, &c., at Persepolis and the Assyrian sculptures. There is no doubt a distinct but not a direct connection. The great bulls of the Propylæa of Xerxes and the lions and winged gryphons are evidently designed on direct inspiration of Assyrian work. The Assyrian palaces were in all probability in ruins in the time of Darius, and could hardly have furnished the sculptors with models. Also it is to be noticed that there are several marked deviations from the Assyrian design, as in the peculiarly disproportionate heads of the winged bulls and the very conventional forms of the lions in the friezes. The explanation is now, however, accessible. Just as the Vannic kings had borrowed their writing from Assyria, in like manner they borrowed their art. The antiquities discovered at Toprak Kaleh, bronze thrones, shields, &c., part of which are in the museums in London and Berlin, present the very peculiarities which are found still

more exaggerated in the work of the sculptors at Persepolis. Thus, then, the art of Armenia is the work which connects the art of the Achaemenian kings with that of Nineveh, and it will be seen that, after all, the ancient kingdom of Armenia, whose history was lost for centuries, played no mean part in the drama of empires some twenty-eight centuries ago. There can be little doubt that, like many other parts of Asiatic Turkey, it would be a rich field for archæological research could the Porte be induced to grant the necessary permission.

TESSERÆ.

Glass Cameo Cutting.

THE processes by which the Portland and Auldjo vases and many others were executed is exceedingly interesting, consisting as they did of a combination of the art of the gem-cutter with the artificial formation of the gem on which he worked. A lump of blue glass, for instance, having been taken on the end of the glass-blower's pipe was immersed in a molten mass of white glass, and the two gradually distended by blowing through the pipe, the twirling of the pipe and the touching of the partially-blown mass of glass at its end gradually shaping the vessel into its perfect vase-like form. Having been allowed to cool, the glass-maker's art had provided a vase in two thicknesses of differently-coloured materials, which, being exposed to the action of the glass-cutter's wheel, allowed of the removal of so much of the external white coating as left only a comparatively small portion of the white to show as a cameo upon the blue. A further series of operations analogous to those of the gem-cutter reduced the white silhouette to a perfectly-modelled bassissimo rilievo, this latter operation being precisely similar to the gem-cutter's usual dealing with a striated onyx or other similarly laminated mineral. It is curious to find an exactly similar process of glass-working and cutting in use from the earliest ages in the East, particularly in China, and the elaboration with which the Chinese occasionally worked, and still work, through three or four layers of differently-coloured glasses is quite extraordinary. In their practice, however, much more seems to have been left to chance than in the practice of the Greeks and Romans, since we usually find in old Chinese works of these kinds that the glass-worker has made up his vessel originally of pieces of differently-coloured glasses, sometimes overlying one another, and sometimes going completely through the whole thickness of the vessel. The ingenious Chinese glass-cutter took advantage of all these accidental thicknesses and crossings of differently-coloured materials to detach one from the other by extraordinary undercuttings, finishing the irregularly-shaped projections into any fantastic form which they suggested to his lively imagination.

Masonry and Freemasonry.

The first great event in the art of masonry was the building of the Tower of Babel; this expressed figuratively the attempt of some unknown mason to build up the temple of the Holy Ghost in anticipation of Christianity, which attempt however had been confounded by the vanity of the builders. The building of Solomon's Temple, the second great incident in the art, had an obvious meaning as a prefiguration of Christianity. Hiram, simply the architect of this temple to the real professors of the art of building, was to the English Rosicrucians a type of Christ; and the legend of masons, which represented this Hiram as having been murdered by his fellow-workmen, made the type still more striking. The two pillars also, Jachin and Boaz (strength and power), which are amongst the memorable singularities in Solomon's Temple, have also an occult meaning to the Freemasons which cannot be publicly explained. This symbolic interest to the English Rosicrucians in the attributes, incidents and legends of the art exercised by the literal masons of real life naturally brought the two orders into some connection with each other. They were thus enabled to realise to their eyes the symbols of their own allegories; and the same building which accommodated the guild of builders in their professional meetings offered a desirable means of secret assemblies to the early Freemasons. An apparatus of implements and utensils, such as were presented in the fabulous sepulchre of Father Rosycross, were here actually brought together. And accordingly it is upon record that the first formal and solemn lodge of Freemasons on occasion of which the very name of Freemasons was first publicly made known, was held in Masons' Hall, Masons' Alley, Basinghall Street, London, in the year 1646. Into this lodge it was that Ashmole the antiquary was admitted. Private meetings there may doubtless have been before; and one at Warrington (half-way between Liverpool and Manchester) is expressly mentioned in the life of Ashmole; but the name of a Freemasons' lodge, with all the insignia, attributes and circumstances of a lodge, first came forward in the page of history on the occasion just mentioned. It is perhaps in requital of

the services at that time rendered in the loan of their hall, &c., that the guild of Masons as a body, and where they are not individually objectionable, enjoy a precedence of all orders of men in the right to admission, and pay only half fees. Ashmole, as one of the earliest Freemasons, appears from his writings to have been a zealous Rosicrucian. Other members of the lodge were Thomas Wharton, a physician, George Wharton, Oughtred, the mathematician, Dr. Hewitt, Dr. Pearson, the divine, and William Lilly, the principal astrologer of the day. All the members, it must be observed, had annually assembled to hold a festival of astrologers before they were connected into a lodge bearing the title of Freemasons. This previous connection had no doubt paved the way for the latter.

Historic Painting.

The historic painter does not neglect or contravene nature, but follows her more closely up into her fantastic heights or hidden recesses. He demonstrates what she would be in conceivable circumstances and under implied conditions. He "gives to airy nothing a local habitation," not "a name." At his touch words start up into images, thoughts become things. He clothes a dream, a phantom, with form and colour, and the wholesome attributes of reality. His art is a second nature, not a different one. There are those, indeed, who think that not to copy nature is the rule for attaining perfection. Because they cannot paint the objects which they have seen, they fancy themselves qualified to paint the ideas which they have not seen. But it is possible to fail in this latter and more difficult style of imitation, as well as in the former humbler one. The detection, indeed, is not so easy, because the objects are not so nigh at hand to compare, and therefore there is more room both for false pretension and for self-deceit. They take an epic motto or subject, and think that the spirit is implied as a thing of course. They paint inferior portraits, maudlin lifeless faces, without ordinary expression or one look, feature, or particle of nature in them, and think that this is to rise to the truth of history. They vulgarise and degrade whatever is interesting or sacred to the mind, and think that they thus add to the dignity of their profession. They represent a face that looks as if no thought or feeling of any kind had ever passed through it, and would have you believe that this is the very sublime of expression, such as it would appear in heroes or demi-gods of old, when rapture or agony was raised to its height. They show you a landscape that looks as if the sun never shone upon it, and tell you that it is not modern—that so earth looked when Titan first kissed it with his rays. This is not the true ideal. It is not to fill the moulds of the imagination, but to deface and injure them; it is not to come up to, but to fall short of the poorest conception in the public mind. Such pictures should not be hung in the same room with that of "Blind Orion hungry for the morn."

Italian Enthusiasm for Art.

It is in the great monuments and permanent museums of Italy that we learn to recognise how inseparable the perfection arrived at in these minor arts was from that greater sublimity attained in the noblest efforts of the architect, the painter and the sculptor. It is precisely in this union of imagination of the loftiest kind with perfect technical dexterity in art productions, on either the vastest or the most minute scale, that the great strength of the excellence of the finest Italian design in old time consists. All these relics, whether taking the form of gigantic churches, of stately palaces, of heroic works of sculpture, of extensive frescoes, of elaborate furniture, of pottery, glass and even ornamental leather, show how absolutely indispensable to personal enjoyment art then was. Every student of the "Divina Commedia" must remember the almost passionate terms in which Dante mourns over that transition from simplicity of life and manners to a luxurious indulgence of the intellect and senses, which no sumptuary laws, however stringent, were ever able to subdue. Long and vainly the nobles strove during the fourteenth and fifteenth centuries to preserve for themselves a monopoly in splendour, but wealth accumulating in the hands of the citizens ultimately broke up their ineffectual blockade. How and with what results may be traced in the chronicles of Villani and Corio; in the excellent "Discorso di Guglielmo Manzi sopra gli spettacoli, le feste, ed il lusso degli Italiani nel secolo XIV.;" and in Muratori's grand collection of writers "rerum Italicarum." Out of the superabundant gains of the industry and commerce of Florence, Sienna, Genoa, Venice, Lucca, Pisa and Milan, and out of the accumulated riches drawn by an all-powerful priesthood from its spiritual tributaries in all parts of the world, one cannot fail to be struck with the very large proportion which was obviously expended in supplying this apparently insatiable craving for beauty. Sums of money which would frighten the nobles, commercial or hereditary, even of this kingdom, were lavishly expended on the great monuments of Italian art. Taking, for instance, such a city as Palermo, we find, even at the present day, not tens, but twenties and thirties of churches lined throughout with marble mosaic of the most costly description. The riches at

St. Mark's at Venice, St. Peter's at Rome, the Certosa at Pavia, St. Anthony at Padua and the churches of the Annunziata and San Matteo at Genoa, appear almost beyond estimation; while not only in monuments such as adorn these cities is the boldest dimension and the grandest scale adopted, but every inch of wall surface and every piece of church furniture, however insignificant, is made as elaborate as human ingenuity and human hands can make it. To such an exuberant extent was this apparent craving for enrichment indulged, that where, as happened in many cases, funds were wanting to complete the ambitious designs of the founder of some great monument, his successors, rather than leave the work altogether unfinished, have endeavoured to realise by paint and every kind of ingenious expedient the effect so ardently desired by the original founder of the edifice. Hence proceed many of those illusive perspectives which almost convert flat ceilings into airy cupolas, and carry out the eye of the visitor in the *salone* or grand apartment of the *piano nobile*, or principal floor of an Italian residence, through apparently interminable arcades to an exuberant landscape alive with statues and fountains.

The Royal Exchange.

The general impression is one of ornamental heaviness, with a display of wealth certainly, but which had not been fortunate in securing the guidance of good taste. The best appearance is undoubtedly that presented towards Cheapside, whence the tower and cupola combine agreeably with the portico; but the latter is out of keeping with the rococo style of dress that prevails in other parts. The fenestration in particular is open to much question. The circles inscribed within other circles that are not concentric to them, as in the east front, engender an unpleasing mixture of plane and spherical trigonometry, very perplexing to those who have only time for the monetary calculations applicable to the *locus in quo*. Then again in the interior court the windows of the upper floor fatigue one with corresponding want of symmetrical arrangement. There is first a great semicircle coving round a smaller one, within which a triangular pediment is awkwardly introduced; below that a square, then again another semicircular head inscribed in this square, whose spandrels thus abridge the light which would have been welcome to the chambers within. In the court below the engaged Tuscan columns supporting an entablature no wider than their own capitals, which merely starts out from among the *voussoirs* of the arches of the colonnade, have a singularly ungracious and anomalous aspect. The columns, in fact, both within and without are an additional instance of the difficulties that unavoidably attend their introduction into the buildings such as our times and usages require. If they are dipteral our rooms must be lit in some other way than they usually are; if they are engaged, *i.e.* merely decorated piers on the face of the wall, we then see two or more rows of windows squeezed in between them, and close underneath a cornice to which they are necessarily so near that it becomes uncomfortably oppressive. This is the case at Cornhill, in proceeding along which the eye is caught by the protruding window-sills and dressings, just disturbing the vertical cylindrical lines of the columns.

Opie and Northcote.

When Opie was engaged on his picture of the death of James I. of Scotland, Northcote, who was his imitator and rival, became alarmed at the reports which reached him of its extraordinary merit. The uneasiness produced by his jealous fears drove him to pay a visit to the studio of Opie, that he might judge for himself. "When I entered the room," he says, "I was astounded. The picture had the finest effect I ever witnessed; the light on the figures gleamed up from below a trap door by which the murderers were entering the King's chamber. 'Oh,' I said to myself, 'go home, go home; it is all over with you.' I did go home, and brooded over what I had seen. I could think of nothing else; it perfectly haunted me. I could not work on my own pictures for thinking of the effect of his. At last, unable to bear it any longer, I determined to go there again; and when I entered the room I saw, to my great comfort, that Opie had rubbed all the fine effect out."

The City and Foreigners.

We read in the "Acta Regia," "The Italian merchants and owners procured that part of the City of London on the north side out of Tower Street, called Minchin Lane, to build upon for their lodgings and storehouses, as the merchants of the Haunce of Almaine were licensed to have an house called Guilda Teutonorum, the Guildhall of the Germans; the merchants of Bordeaux were licensed to build in the Vintry strongly with stone, as yet may be seen, and seemeth old though often repaired. A spot near Mincing Lane was the manor of Blanch Apleton, where, in the 3rd of Edward IV., all basket-makers, wire-drawers, and other foreigners were permitted to have shops. Blanch Apleton is corruptly called Blind Chapel Court; it was a manor belonging to Sir Thos. Roos, standing at the north-east corner of Mart Lane, so called from the privilege of keeping a mart there, but now called Mark Lane."

NOTES AND COMMENTS

WE lately referred to the litigation which arose in connection with a boundary-wall forming part of the premises of the Sun Assurance Company in Glasgow, of which we published an illustration last week. The owners of the adjoining ground proposed to use the wall as a party-wall and to erect on it a building 51 feet in height. As opposition was raised the case was tried in the Sheriff Court and judgment was given in favour of the Sun Assurance Company on the ground that there was no such absolute right to the use of the wall as was claimed. The other parties appealed and the case came before four of the judges in Edinburgh, when it was declared that the boundary-wall was a mutual gable-wall. The case was ordered to be sent back again to the Dean of Guild Court in order to have it determined whether the plans of the proposed building can now obtain approval. There would be much advantage if the case could be brought to the House of Lords, for if the judgment of the Edinburgh Court is not overruled it will have an effect on building in Scotland which will not be altogether advantageous.

AN appeal has appeared from Sir GEORGE BIRDWOOD soliciting relics and memorials of the East India Company for exhibition in May at Earl's Court. The classes desired are:—1. Portraits, which will chiefly be engravings, of notable members of the company, or of servants of the company and other persons who distinguished themselves in the company's service. 2. Paintings, drawings, sketches, or engravings of buildings or scenes connected with the company's history; or of memorable events or actions or episodes connected with the same; or illustrating life in India under the company's rule, particularly its romantic side. 3. Original maps and plans of battles and manuscripts, particularly letters of special interest relating to India, by distinguished Anglo-Indians. 4. Seals, and impressions of seals, when these are distinct, and naval and military flags and colours, and stamps and impressions of the company's "bale mark." 5. Medals given by the company and coins issued by them prior to 1858. 6. Naval and military uniforms of the company, and arms, particularly those bearing the company's "arms" or their "bale mark;" the silver badges of their boatmen and the truncheons of their constables. 7. Swords of honour and presentation plate. 8. Furniture and marble bas-reliefs and statuary, from the old East India House, removed from it in cartloads to "the four imagined corners of the world." The East India Company was formed in 1599 with a capital of about 30,000*l.*, and the first charter was granted in the following year.

HIS meritorious services to the State in connection with the National Portrait Gallery earned a knighthood for the secretary, keeper and director. Sir GEORGE SCHARF deserved honour on other accounts. In his prime he was one of the few artists who could produce satisfactory figures in outline, and hence his drawings of antique statues are always satisfactory. He was no less competent to suggest the character of paintings, as will be seen by his illustrations of KUGLER'S "Handbook." In the woodcuts of such books as Dean MILMAN'S "Horace" and MACAULAY'S "Lays of Ancient Rome" his refined and accurate drawing is at its best. His superiority to ordinary draughtsmen will be apparent to all who compare his work with G. F. SARGEANT'S in Bishop WORDSWORTH'S "Greece." Sir GEORGE SCHARF was born in London in 1820, and educated at University College School. After gaining medals at the Society of Arts, he was admitted a student of the Royal Academy in 1838. His first published work was a series of etchings entitled "Scenic Effects," illustrating MACREADY'S revivals at Covent Garden Theatre. He travelled through Italy and various parts of Asia Minor in 1840-43, as draughtsman to a Government expedition. Many of his drawings are now in the British Museum. He was art secretary to the Manchester Exhibition of 1857, and in the same year was appointed Secretary and Keeper of the National Portrait Gallery. Among his writings are a "History of the Characteristics of Greek Art," prefixed to WORDSWORTH'S "Greece;" Descriptions of the Greek, Roman and Pompeian Courts at the Crystal Palace,

"Artistic and Descriptive Notes on Remarkable Pictures in the British Institution Exhibition of Ancient Masters" (1858), "Catalogue of Pictures and Works of Art in Blenheim Palace," "Catalogue Raisonné of the Pictures belonging to the Society of Antiquaries, London," "Catalogue of Pictures at Krowsley," "On a Votive Painting of St. George and the Dragon," &c. He is likewise the author of an historical account of the pictures belonging to the Crown, tracing their vicissitudes from the reign of HENRY VIII. to the present century. In 1882, after a service of twenty-five years, Sir GEORGE SCHARF was constituted Director of the National Portrait Gallery.

CORPORATIONS cannot expect to be able to erect large buildings of an experimental kind and be free from claims for extras unless in the contracts they have allowed contractors ample sums to provide for all the contingencies which can be imagined. The new labourers' dwellings in Manchester do not correspond with the Waterlow or Peabody buildings in London, and there were no precedents for some of the arrangements. The builders claim 7,383*l.* on the Oldham Road blocks, and 5,535*l.* on those in Pollard Street. The sums are large, but it may be they were unavoidable. The sanitary committee of the City Council having charge of the work stipulated that no extras should be ordered without their written consent. It may, therefore, be assumed that the stipulation was observed. The explanation of the architects has to be given, and until it is considered the responsibility cannot be assigned, but if there were irregularities, the Council will not readily condone them.

ON Monday Mr. SILVANUS TREVAIL, architect, mayor of Truro, was presented, through the Lord-Lieutenant of the county, with a testimonial, for which subscriptions were obtained from all parts of Cornwall. It consisted of a dinner, tea, coffee and dessert service, a seven-light candelabra and other articles, mostly silver, and a cheque for 100 guineas. The salver bore an inscription beneath the Mayor's crest and the county and borough arms, stating that the testimonial was presented in grateful recognition of the valuable services rendered by Mr. TREVAIL to the county during the parliamentary session 1893, in the railway development of Cornwall. Mr. TREVAIL, in returning thanks, said he was exceedingly proud of the recognition of his services to the county which had fallen from the Lord-Lieutenant. That railway business had to be done publicly, and he could not help his personality being prominent in it. But he had worked harder for other things. He worked harder for a harbour of refuge on the north coast, and he remembered going with a deputation, headed by the Lord-Lieutenant, to Mr. CHAMBERLAIN, when that gentleman was President of the Board of Trade. Mr. CHAMBERLAIN, he thought, received them coldly, and in a nonchalant manner seemed to say, "I am President of the Board of Trade; I shall do what I like in the matter. Good-bye." But during the last week had we not cause to wish that something could be done to provide a harbour of refuge on the north coast? There was another way in which they could save more lives than even by a harbour of refuge, and that was by improving the sanitary conditions of the county. It was only by careful study that one could get an adequate conception of the loss of life through insanitary conditions. Although Cornwall already had one of the lowest death-rates, it might still be reduced by two or three per 1,000, and that, on a population of 300,000, meant saving 600 or 700 lives a year. Moreover, if they could prove that their peninsula was the healthiest part of the British Isles, with the most favourable and most equable climate, they would get such a residential population there as would compensate them for their losses in mining, agriculture and fishing, and that would be a permanent interest which detracted nothing from the county like mining. The county had splendid coast scenery, second to none, and having these natural advantages why should they not take every opportunity of showing them to the rest of England and inducing people to come to them? This was a work not only for themselves, but for the future benefit and prosperity of the county. When they saw mine after mine closing they must get some new interest to take the place of mining.

COUNCIL CHAMBER, NEW TOWN HALL, BURTON-ON-TRENT.
NEW TOWN HALL, BURTON-ON-TRENT.

A FEW years ago we published a view of the St. Paul's Institute in Burton-on-Trent, which was erected at the cost of the late Mr. M. T. BASS, from the designs of Mr. REGINALD CHURCHILL, the cost being 46,000*l*. In 1891 Lord BURTON, interpreting the wishes of his late father, offered the buildings as a town hall, and in addition proposed to add a suitable council chamber which would cost about 17,000*l*. Expenditure on other works was also needed, and the group of buildings may be valued at 85,000*l*. If the other buildings presented to the town by the late Mr. M. T. BASS and Lord BURTON be included, the gifts represent an outlay of 172,000*l*. The new wing, which contains the council chamber, has been carried out in Late Decorated style throughout, and is built with best red facing bricks from Messrs. J. KING & Co., of Stourbridge, and with Ancaster stone dressings on the exterior, the whole of the interior—corridors and staircases—being faced with Corsehill and Mansfield Woodhouse stones. The Corsehill is used for dados, cornice, door and window-joints and arches, and the Mansfield for ashlar-work generally. The combination of these two stones has worked out most effectively and satisfactorily. The general arrangement of the reception-rooms and offices is as follows:—The mayor's entrance under the tower gives access to a spacious hall with porch, separated by glass screen doors with the town arms thereon in brilliant cut glass. A porter's lodge is provided here and a small waiting place. These are enclosed by an arcading of three arches, supported on massive polished red granite bases and shafts. The town surveyor's private office and two of his drawing offices open out into the hall, and a connection with the public or town hall is also provided. The grand staircase provides communication with the council offices on the first floor. The whole of the staircase has been faced with Mansfield Woodhouse stone about three-quarters of an inch in thickness, doweled in every course with copper holdfasts to the old wall, and finished with a deep frieze of tracery and a carved cornice in Corsehill stone. All the old timber-work of the doorways has been pulled out, and enriched joints and pediments out of Corsehill stone substituted. New archways have been cut, other openings closed up and practically a new building, so far as the interior is concerned, has been constructed. Two cloak-room lavatories, tiled throughout on the walls by Messrs. MINTON, HOLLINS & Co., of Stoke, have been provided off the staircase and fitted up in the best style with oak screens, Devonshire marble ranges and TWYFORD'S best basins and other apparatus. Two committee-rooms are provided on the upper floor, together with the mayor's parlour, finished in wainscot oak, and his worship's retiring-room. The town clerk's office is in close contiguity to the council chamber and is a large and well-lighted room, from which access is obtained at the north end to another corridor, with separate staircases to the lower floor and to the public entrance from the street. In this corridor are arranged three offices for the town clerk's staff, strong-room, stores, lavatory and office for the medical officer. Two spare offices are provided on the second floor.

On the ground floor of the new wing, which has a separate entrance from the street, are the public rates office, borough collector's office and additional accommodation for the borough surveyor's drawing staff, together with offices for the sanitary inspector and borough inspectors, and for the borough accountant and his staff. A house for the caretaker, with parlour, living-room, scullery and five bedrooms is also incorporated with the block of offices. Spacious cellars, vaults for heating and the electric transformers, coals, &c., are provided in the basement.

The council chamber, 53 feet by 30 feet and 21 feet in height, is panelled in oak throughout from floor to ceiling, fumed and wax polished, and the whole of this work has been executed by Mr. J. THOMPSON, of Peterborough. It is divided into five bays at the sides and three at the ends. Nine of the side bays are filled with three-light windows, enriched with stained-glass, and contain shields charged with the armorial bearings of the mayors who have passed the chair since the charter of incorporation, and continued

by other shields charged with St. George's cross, to be removed and filled as other mayors succeed to civic responsibilities. The east end of the room is divided from the main part by three arches, and is apportioned to the public who wish to attend the debates of the council, a separate access thereto with stone staircase being provided. The whole of the oak-work is elaborately finished and carved, and an inscription notifying the fact of Lord BURTON'S gift to the town is introduced at the west end.

MESSRS. HARDMAN & POWELL, of Birmingham, are responsible for all the polished bronze fittings and furniture, and Messrs. HOMAN & RODGERS, of Manchester, for the polished oak-block floor, as well as for all the fireproof floors throughout this building.

The oak furniture for this room is also provided by Lord BURTON.

The town hall portion of the premises has not been considerably altered from its original state as St. Paul's Institute. Thorough renovation has been carried out, and new oak panelled and traceried porches have been erected at the main entrance. This room—80 feet by 40 feet—contains a fine organ by KIRKLAND and a permanent orchestra. There are also seven anterooms attached, large kitchen, scullery, larder, wine-room, &c., and every convenience in the shape of glass, earthenware, linen, electro-plate, &c., to dine 300 persons. Attached to this portion of the building is the annexe or reception-room—63 feet by 23 feet 6 inches—which can also be used for suppers at balls or other large functions. The whole of the works have been carried out by Messrs. THOMAS LOWE & SONS under the architect's personal superintendence, with Mr. S. NEEDHAM as clerk of works.

Among the contractors are Messrs. NICHOLLS & CLARKE, of Shoreditch, leaded lights and other glass-work; CHAMBERLAIN, KING & JONES, furniture; MILNER & Co., safes; GEORGE PRICE, LIMITED, strong-room doors; T. RODDIS, carving; and BEESTON FOUNDRY Co., Nottingham, radiators.

ENTRANCE HALL, THURLAND CASTLE, KIRKBY LONSDALE.

THE ARCHITECTURAL ASSOCIATION.

THE ordinary meeting of the Association took place on Friday evening, the president, Mr. E. W. Mountford, in the chair.

Mr. T. W. Aldwinckle, jun., was elected a member.

Mr. W. SAMUEL WEATHERLEY read a paper on

Architectural Perspective.

Mr. Weatherley said:—The making of an architectural perspective mostly presupposes the drawing of that which does not yet exist, and one may add parenthetically, never may exist. Thus it is that the perspective has to be worked from geometrical drawings from plans, elevations and sections, and I expect I have been asked to try to tell you to-night what I can about the methods I have used, the practical rather than the theoretical side of the question—at least, this is the interpretation I have put upon the invitation of your committee. I do not think I need apologise for doing so when we consider that the scientific side has so often to admit the absurdity of its results; in fact I very much doubt whether perspective can, strictly speaking, be brought down to rules, certainly not hard and fast ones, for there is scarcely a rule but has to be broken, and therefore the best course it seems to me to be thoroughly grounded in a few broad principles which must be used with a large proportion of that useful article known as common sense. The very first day of my pupillage I was set to work upon perspective, and this without any previous knowledge from books, and a very fortunate circumstance I have always considered it. I doubt much whether anybody ever learnt from books alone anything of practical use; those I have met who have tried have certainly failed. Two books I have lately looked through, one "Modern Perspective," by Mr. W. R. Ware, published at Boston, U.S.A., in 1883; the other, a more recent publication, I believe the very latest and in the library of the Institute, to which I shall presently refer. The first book is a scientific and practical work written in precise and clear language. I am bound to say it interested me greatly, for Mr. Ware was an old member of the Spring Gardens Sketch Book. It almost seems as if some of the dodges in use when I was with Sir Gilbert Scott might have originated from

him. For instance, what he calls in his book the "method of diagonals" and the "method of triangles."

It may help you to understand my subsequent remarks if I just run through the terms used, more or less customary no doubt, when working from a plan.

1. *Point of Station*.—The point where the spectator stands, i.e. the eye of the spectator.

2. *Visual Rays*.—Rays from the point of station.

3. *Centre Visual Ray*.—A line from the point of station bisecting the angle formed by the two extreme "visual rays," forming, in fact, the centre line or focus of the perspective view.

4. *Point of Sight*.—The point where the "central visual ray" first cuts the building.

5. *Picture Plane*.—A line or vertical plane at right angles to the central visual ray (used with reference to the plan).

6. *Vanishing Points*.—Points at which all lines that are in reality parallel must vanish.

As a rule vanishing points are on the horizontal line.

In what is called parallel perspective, where one side of the building is parallel to the picture plane, and therefore has no vanishing point, the vanishing points for the other sides will be found to coincide with the point of sight.

7. *Horizontal Line*.—This is always the level of the eye (used with reference to the perspective).

8. *Height Lines*.—Lines erected vertically on the horizontal line for the purpose of measuring off the heights to the same scale as the plan.

I think I can best illustrate these if I take the "point of station," "visual rays," and the "picture plane," and apply them. For a beginner it is by far the better way, in my opinion, to determine the "point of station" on the spot, and to do this you must select a building which exists, and of which you must also have the geometrical drawings. There will be some important feature you wish to emphasise in your view; see that this groups with the other features, and whether improved by standing rather close in or further away; then notice where your eye appears to rest, looking full to the front, the central visual ray forming as it were the focus of your view, and then imagine between yourself and the building a sheet or plane of glass—the picture plane—upon which you might trace the view at once, every line vanishing to its proper vanishing point. The distance between yourself, that is, the "point of station," and the sheet of glass is a movable feast, and only affects the size your tracing would be. I am aware the picture plane is an artificial invention, for no doubt we view things as seen upon a surrounding transparent sphere, as if we stood in the middle of a gigantic soap-bubble. When you have these things determined and fixed in your mind, transfer them to your plan to the same scale as your plan, and you will have learnt some vital requirements which give you successful command for all that follows. If the building does not exist, or you cannot get to it, you must go through the same operation in imagination, using the plan and other drawings, bearing in mind that from the "point of station," as far as the building is concerned, the eye can only take in an angle of about 60 deg., that is, 30 deg. either side the central visual ray, and this applies also to vertical heights with certain modifications, such as the upper part of spires, which may somewhat exceed this angle. We know, therefore, pretty much how near we may stand in, and how far off we stand is governed somewhat by the nature of the building, whether picturesque or severe in character; standing too near brings about an acute result, too far a tame result. As a rough general rule, the distance from the nearest angle of the building is found to be about one and a half to twice the width comprised between the two visual rays that cut the extreme points of the building on the "picture plane," but there is no golden rule; it is a matter of judgment which experience alone can teach, and it can most easily be acquired by working back from an existing building, and for a beginner it enables him to identify and realise what the "point of station," "central visual ray," and "picture plane" really are when drawn on the plan.

To exemplify this, and to show how easily everything else follows—vanishing points, horizontal line, height lines, &c.—I will take a simple case, such a building, for instance, as the Cloth Hall at Ypres, in Flanders, a building with façade some 460 feet long, flanked by two corner turrets, and with a central tower 230 feet high. Suppose we stand about 650 feet away, determining the position and distance for the reasons already stated. From the "point of station" draw lines on rays to the extreme points of the building, bisect this angle, the bisecting line being the "central visual ray," and then draw the "picture plane" at right angles to it, and if drawn as shown on the diagram, the point where it cuts the building will be the same scale as the plan from which you are working, necessarily so for all vertical heights at this point, and hence a height line.

Of course the "picture plane" could be either nearer or further away from the "point of station," according to the size the drawing is intended to be. Objects lying at the same distance as the "picture plane" are of the same scale as the plan; objects behind have their perspectives smaller, being conically

projected forward upon it; and objects in front have their perspectives larger, being conically projected backward upon it. The "picture plane" is the line upon which all perspective widths and depths are measured; the measurements being taken from just where the lines or rays drawn from the "point of station" or the eye to any point of the building cut the "picture plane." Whether the "picture plane" is behind the plan of the building, and the rays have to be extended—conically projected backward upon it—is immaterial, and I may remark in passing that I have found it convenient to draw the rays without reference to any points on the plan, except perhaps a few salient ones, drawing them pretty closely together, if in ink or pencil then occasionally a red one among them, and by doing so you will find the eye will readily follow any point on the plan, either up or down to the "picture plane," and then can be measured off with more accuracy than if the rays had been drawn to each particular point; and the rays need not be drawn further than you like on the "point of station" side of the "picture plane," nor beyond the limits of the plan on the other side, unless additions are likely to be made to the plan in the fore or back-ground; the object being to get all your leading lines from the plan on to the "picture plane," and thus have done with the "point of station," and you will be very glad to do so, as it is mostly a long way off the paper, and very probably the drawing-board. The next thing to do is to find the vanishing points, and this is simply mechanical, because, having arrived so far, they give themselves thus—draw a line from the "point of station" parallel to the side of the building for which you want the vanishing point, until it cuts the "picture plane," and where it cuts it will be the vanishing point required, and it can be measured off, say, from the "central visual ray," and transferred to the "horizontal line;" and, if you remember that all lines in reality parallel must vanish to the same vanishing point, it will clear up any confusion that might at first arise, for you have only to repeat this operation for any side of your building at whatever angle it may be. "Height lines" can be erected on the "horizontal line" at any point where the building cuts the "picture plane." If the "height line" is wanted at a part where the building is beyond the "picture plane" or on the "point of station" side of it, all you have to do is to produce upon your plan any side or face of the building in the same straight line until it cuts the "picture plane," and at the point where it cuts set up your "height line," and measure your heights upon it to the same scale as your plan, working back your heights to the vanishing point for that side of your building just produced until they cut the desired parts. It was while struggling with the difficulties of an exterior and uncertain as to "height lines," that a fellow pupil turned round on his stool, and holding up about three-quarters of the length of his pencil, asked pathetically whether that was a fair height for the spire.

You will find in practice that it is best to make a height line do as much work as possible, and not employ too many; you will soon find out what is best to be done as the cases arise. The rules which I have run through and explained by the diagrams are sufficient to enable you to make an architectural perspective, but their extended application is more intricate, and herein lies the resource and skill of the draughtsman. Before attempting to describe any of these refinements, I will just refer to the second of the two books on perspective I looked through, the one recently published. If you come across it you will know it, because in every diagram the "picture plane" is drawn in no case at right angles to the "central visual ray," the necessity for which cannot be too strongly impressed otherwise the perspective will be distorted. I remember the street front of an otherwise fine drawing, outlined for Mr. Brewer to colour, having the appearance of looking round at one. I believe in this case the temptation was to show deeply-recessed arches, and at the same time convey the effect of great length to the façade. Another singularity in the book is that the "picture plane" is always drawn as touching the angle of the building nearest to the "point of station," and this is taken as the height line for all the vertical heights. Neither of these cases is wrong, but the former restricts the size of the view and fails to impart very necessary information, and the latter in practice would not simplify but lead to inaccuracy. No warning is given about an angle of 60 deg. or any other angle being all that can be included, nor a hint of how to avoid the extremities of a building becoming distorted. I think I need not mention the author's name, for you will not require to seek his book, and I have told you how to know it should it happen to fall in your way. I have been showing how to find the vanishing points, and for those that come upon the paper or drawing-board upon which you are making your perspective you cannot do anything better or have them more conveniently to your use; but for those that come a long way off and are outside the drawing-board it is not worth while to find them at all. The vanishing points are of no value; it is the angle at which the lines vanish that is wanted, and this can be found in several ways, thus:—

Divide the distance on your plan between the "point of

station" and the "picture plane" along the "central visual ray" into, say, five equal parts, and from the fourth part counting from the "point of station," produce a line parallel to the side of the building for which you require the vanishing angle until it cuts the "picture plane." Erect a vertical line A at this point, and also a vertical line B where the "central visual ray" cuts the "picture plane"—both lines the same, but of any convenient height. Divide the line B, which is the "central visual ray," erected vertically, into five equal parts, being the same number as you have already divided the distance between the "point of station" and the "picture plane," and from the top of the fourth division draw a line parallel to the "horizontal line," cutting the line A. If a line be then drawn from the point at the top of the fifth division on the line B to the point where the line parallel to the "horizontal line" cuts the line A, it will form with the "horizontal line" the perspective angle required. If I complete the process through the five divisions you will see that each of the right-angled triangles is, as far as their sides are concerned, one-fifth the length of the total angle. Or you may divide both vertical lines A and B into five equal parts, and, having done so, draw a line from the top of the fifth division on the line B until it cuts the line A at the top of the fourth division, and the same result will be obtained. This line, if produced, cuts the "horizontal line" at the "vanishing point" for the side of the building with which we are dealing. A centrolinead can be set to the above perspective angle—that is if you use one, I have not for very many years—or you can run the line to the edges of your paper, and form a scale on both sides; then the left or right hand one or both can be some definite scale upon which heights may be measured off.

Another way of getting at the angle for the far-vanishing point, commonly practised at Scott's, was to erect two vertical height lines on the "horizontal line," one A being, say, where the "picture plane" cuts the side of the building, having the far-vanishing point, and the other B where a line produced at right angles to the same side from any point some way down the side cuts the "picture plane." Then we should set up equal heights on both, and run the far one B down towards the near vanishing point, which you must have already found and marked on the "horizontal line" until it cuts a vertical line C, erected over the point on the "picture plane," where the "visual ray," from the "point of station," cuts it on its way to the point from whence the line which gave the point B was produced. Having done this, draw a line from the top of the height line A to the point where the height line B cuts the vertical line C, and you will have the perspective angle given you. A very foolish way, but gravely undertaken in my pupilage days, was to produce the "picture plane" and a line from the "point of station" parallel to the side of the building having the far-vanishing point until they met; not infrequently through a doorway from one office to another, and for this purpose we kept a huge ball of string. Then the angle was taken, the centrolinead set and the view begun. I recollect during my pupilage making a perspective for a competition of the exterior of a building in Mark Lane. We fixed the "point of station" some 300 feet away, on the other side of the Lane, and the vanishing point for the front was found by the means I have just described. There are the useful, in fact, indispensable, 45 deg. vanishing points. These are found in precisely the same way, that is, a line parallel to the 45 deg. side and drawn from the "point of station" until it cuts the "picture plane," and then transferred to the "horizontal line." The far one can be got from one of the divisions on the "central visual ray" on the principle used for the far vanishing point of the building. For diagonals of towers, for the setting out of pavements, divisions of bays, and for the sides of octagons, &c., these points are, as I have said, indispensable. When a 45 deg. vanishing point comes very near the "central visual ray," it is not of so much use for objects near the centre of the composition, because the angle it makes with the vertical lines is so acute. Vanishing points for an angle of 60 deg. are obtained in the same way, and are, of course, required for hexagonal forms. Up to the present I have been chiefly referring to exterior views, but the methods hold good in the main for interiors, bird's-eye views and what Mr. Ware alludes to as toad's-eye views. Interiors are frequently drawn in what is called parallel perspective, in which, if a parallelogram, then one side of the building is parallel to the "picture plane," and therefore without a vanishing point, and the vanishing points for the other sides coincide with the "point of sight." It is a mistake to let the "point of sight" be exactly in the centre, but it cannot be very much out of the centre if the view is to be kept in parallel perspective. Mr. H. W. Brewer's very fine interiors are mostly drawn in this way. Personally, I prefer using angular perspective or a judicious blend, for instance, in the near parts where the horizontal lines are obviously getting out of perspective, such as to the beams of a roof or to the pavement. Interiors require management; you may have, for example, the abacus of the capitals on the flanking sides, as they get near you, looking as if they skewed upwards and outwards, although

in reality drawn perfectly horizontally. Or, again, you may have, at the far end, an arcade opposite you in which the columns, as taken from the "picture plane," get wider the further they extend to the right or to the left. I need scarcely say these sort of things have to be corrected to what will satisfy the eye, which you must not forget an outsider possesses and uses with critical effect. Interiors admit of some considerable scope in the latitude and flexibility of perspective rules. Really a very beautiful drawing made to show the octagonal central hall of Sir Gilbert Scott's design for the Royal Courts of Justice is probably unique in this direction, in that it shows seven sides of the octagon. The perspective is reduced and forms the frontispiece to the second volume of Sir Gilbert Scott's "Royal Academy Lectures." Bird's-eye views have the "horizontal line" high up, fixed according to the range of view required; they are troublesome drawings to make, and the vertical heights have a tendency to look too high. The best advice I can give you is to place yourself a long way off and a good way up. Toad's-eye views, to quote Mr. Ware again, are luxuries, except in a mild form; they are, as their name implies, the converse of a bird's-eye view; the mild form is when a building is on rising ground some 30 feet or so above the eye.

I remember going in for the Preston Hotel competition, the site being some 40 feet above the surrounding grounds, which I well knew rose rather swiftly to the plateau for the hotel. I roughed out a view, putting the building 40 feet above the horizontal line, deducting nothing for the level of the eye, and the result was as if I had placed it on a mere hillock, and before I got the appearance I knew it ought to have I had to add another 25 feet. Everyone who has gone through some such experience must be quite aware of the result. What may be the explanation I hardly know, but it is, I think, one of the many illustrations of the attempt to reduce an art to abstract rules which have been pushed too far. As a matter of fact, when we look at a building on a hill we do not keep our eyes fixed into the hill side 5 feet more or less above the ground we happen to be standing upon. This is, however, what the rules of perspective compel us to do. In looking at a building on a hill the "central visual ray" is really thrown up, the "picture-plane" to be at right angles is tilted forward, and as a consequence the vertical lines vanish upwards. Anyone who has stood close under a hill and sketched some tallish building on the summit cannot fail to have drawn the vertical lines converging upwards. There is something very odd about mountains and hills, for if you made a model to scale, for instance, of the Snowdon range, you would find the mountains looked mere absurdities, and it is partly for this reason that engineers and surveyors adopt two scales, the larger one being used for the heights.

During my pupilage I was lent out to Messrs. Bodley & Garner, and from them learnt to work perspectives with two scales, one scale having a twelfth added and used for all vertical heights. For interiors you will find this gives a much juster representation, which you can prove for yourselves from an existing building. The use of diagonals is one of the simplest and most accurate ways of finding centres or dividing up spaces either in odd or even parts; in fact, they can be employed in ways without end. Here are a few applications:—It is evident the diagonals of the squares, or, in other words, the 45 deg. vanishing points, can be used in working out interior views in parallel perspective, so that you may practically dispense with the plan. For instance, you can make a scale across any of the horizontal lines; suppose the total width be 25 feet, and your bays are 15 feet, all you would have to do would be to divide the width into twenty-five parts, take fifteen of them, and by means of the 45 deg. vanishing points, mark this off on the perspective side, and then you have the 15 feet bay in its perspective length. This principle admits of unlimited extension, so that for widths and depths it is quite unnecessary consult the plan other than to know the actual dimensions. This method is, I believe, largely taught among drawing-masters, and adopted by painters and others who will not or cannot understand a plan. I do not think an architect would take kindly to it, and it is useless with angular perspective and for exteriors. Mr. Ware describes a method of triangles which he considers a more direct application of the same principle. It is undoubtedly more direct, and it can be used with advantage when the vanishing point of the third side of the triangle comes conveniently on the drawing-board, otherwise it is a bother, and the ordinary use of diagonals is practically less trouble. Diagonals are also absolutely necessary for putting in circles, either vertically or horizontally, or arches in perspective. You will find the curve on the far side of the arches can for all practical purposes be struck on a line parallel with the "horizontal line," that is, at right angles to a vertical line from the perspective springing. The near side is always a compound curve in drawing; it can be drawn by the hand, struck in by compasses or by means of curves. Remember that both sides of the arch are parts of an ellipse. I am, of course, now speaking of arches composed of segments of circles. Remem-

bering this helps the draughtsman to give the right swing, and to know instinctively how the curves in perspective ought to look, especially for the near side, which is the difficult one.

With respect to circles in perspective, there are two aspects which do not require extraordinary skill to depict, that is when it happens to come a circle pure and simple, or a straight line, every other aspect is an ellipse, but this is cold comfort, for it is almost more trouble to draw an ellipse, irrespective of the difficulty of finding the perspective angle of the major and minor axes; still, it is useful to know how to draw an ellipse, because it helps, as I said before, to give you the right swing.

To Draw an Ellipse.—Let B C be the major axis and D E the minor, bisecting one another at A. From D or E, with the radius A B or A C, strike the circle F G, G F cutting the major axis at F and G (these are the foci). From G strike a circle with any radius less than A C, say G H; then measure off this radius on line C B, from C, at K, as shown. From the centre F, with radius equal to B K, strike a circle, cutting the other circle at H. Find any number of points such as H. F H and H G are together equal to C B.

A sphere, if drawn according to the rules of perspective, becomes an ellipse, whereas spheres under all conditions are as round as a ball.

To work out the "point of station," scale and plan of a building from a photograph or perspective is sometimes of great service. The following is the method I use:—Find three vanishing points, one being a 45 deg. vanishing point or any known angle vanishing point.

Let A B and C be the three vanishing points, B being a 45 deg. vanishing point. Bisect A C at D, and describe the circle A E C. Make angle A D E equal 90 deg or twice angle of 45 deg., join E B and produce to F. Draw F G at right angles to A C. F will be "point of station," F G the "central visual ray," and A C the picture plane.

Angle E F C equals 45 deg., E F A equals 45 deg. Had A D E been made 60 deg. or twice 30 deg., E F C would equal 60 deg., E F A equal 30 deg.

The scale must be determined from some parts of the building the actual sizes of which one either knows or can arrive at from internal or external evidences, such as the courses of brickwork, figures in foreground, height of steps, lengths of down-spouts and various other ways. No architectural photograph should be taken without a vertical scale against the building. English photographers are more negligent in this matter than those abroad.

It is a pity the architectural perspectives at the Royal Academy Exhibition become more and more the work of a few specialists. I admit the difficulty for an architect whose time is fully employed being able to make his own views for exhibition; it is a subject that crops up for discussion every now and then. I can bring to mind a view of the entrance tower and semicircular wing of the Midland Grand Hotel; it was on two sheets of antiquarian paper joined. I was making it just at the time of an outcry that all works submitted to the Royal Academy should be the actual work of the exhibitor, and it moved Sir Gilbert Scott to write to the President pointing out that an assistant of his had spent about a fortnight on his stomach, and asking whether such a penance was required of him. This recalls an experiment made about this time in one of the rooms at Spring Gardens, and the sight of three or four men trying to do their work with maul-stick and easel, some even perched on their stools on the desks.

I have been pleased of late years to see an increasing number of pencil perspective drawings; it is a charming medium for not too large views, and is, I find, very much appreciated by one's clients. The difficulties of reproduction, which no doubt formerly stood in the way, have been quite overcome.

Mr. R. PHENÉ SPIERS proposed a vote of thanks to Mr. Weatherley for his paper, which was seconded by Mr. H. W. Brewer, and supported by Messrs. A. Beresford Pite, Paul Waterhouse, B. F. Fletcher, Arthur Baker, W. G. B. Lewis, and carried by acclamation, and the proceedings terminated.

PRESERVATION OF EGYPTIAN MONUMENTS.

THE following draft scheme for an archaeological survey of the Nile Valley, from the First to the Second Cataract, has been prepared by a committee consisting of Sir Colin Scott-Moncrieff, K.C.M.G., Professor Norman Lockyer, C.B., F.R.S., and Mr. Somers Clarke, with Mr. Alan S. Cole as honorary secretary, representing the Society for the Preservation of the Monuments of Ancient Egypt:—

A.—REGION TO BE INVESTIGATED.

The following list of places is necessarily imperfect, as a close examination of the valley in its whole length has not been made for the purpose of the present investigation.

1. Philæ.
2. Bigga.

3. The adjacent Islands.
4. Arab remains on the east bank immediately south of Philæ.
5. Rock and boulder inscriptions round about, on Bigga, Philæ, Shellal, &c.
6. Dabod. Temple and approach thereto. Quarry in the hill behind.
7. Dimri. Temple. Remains in brick: Coptic? Arab?
8. Markos. Island. Brick remains thereon.
9. Kertassi. Temple. Quarries. Graffiti. Girdle wall within which must be temple remains.
10. Kalabsha. Temple. Quays. Walls. Quarries. Beit el Wali. (Above R. L. 118 mètres.)
11. Tafa. Temple. Houses. Site generally.
12. Abu Hor. Quay wall. Temple?
13. Dandur. Temple. Terrace. Site of town.
14. Gerf Hussein. Rock temple (above R. L. 118 mètres). Approach.

15. Kirsh. Walled town. Coptic church.
16. Koshtemna. Fort. Town.
17. Dakka. Temple. Town.
18. Kuban. Fort. Temple. Tomb pits.
19. Korti. Foundation of temple. Site of town. Mound.
20. Maharaga. Temple.
21. Mahendi. Town. Ruins of Coptic churches. (Above R. L. 118 mètres)
22. Coptic church on west bank near Sebua.
23. Sebua. Temple, partly in rock. Approach. (Temple above R. L. 118 mètres.)
24. Amada. Temple (above R. L. 118 mètres).
25. Derr. Rock temple (above R. L. 118 mètres). Rock tombs, probably below water line.
26. Fort on west side of river.
27. Elesiyeh. Rock tomb (probably above R. L. 118 mètres).
28. Ruins of town opposite Elesiyeh.
29. Aniba. Brick pyramidal tombs and burials of all sorts. (Rock tomb of nineteenth dynasty, above R. L. 118 mètres.) Above this it is supposed that everything will be above the highest level of reservoir.
30. Kasr Ibrim. Roman town. Coptic church with graffiti. Rock tombs. Stele to south.
31. Ermenna. Ancient town and tombs on west bank. Stelæ. Inscriptions. Coptic church on east bank.
32. Abu Simbel. Rock temples. There are, almost certainly, remains of a town just north of this on the west bank.
33. Jebel Adda. Rock tomb. Ruined city on Jebel.
34. Kasr el Wiss. Fort on the hill, probably Arab.
35. Farras on west bank. Rock tombs. Early Coptic texts. Fort, probably Roman. Coptic church opposite side of river.
36. Serreh. Temple of Rameses II. on west bank. On east bank, Egyptian fort, enclosing Coptic church and town.
37. Argin. Coptic church, mound and ruins.
38. Wadi Halfa. Two temples. Ditch cut in rock enclosing temples and dwellings. Tomb. Graffiti.
39. Abusir. Coptic remains, church, &c., just below the rock.
40. Matuka. Egyptian fort. Double walls. Temple of Usertesen III. within. Another fort on the island opposite. Ruins. Coptic? on small island in the middle of the cataract.

In addition to the above antiquities at places named, it must be added that graffiti hieroglyphics, Semitic and Greek, occur on isolated rocks or cliffs on either side of the river. These require careful examination and copying.

We would propose that the survey should commence with a preliminary reconnaissance, providing a general map and maps of sites as detailed in C, to be followed by plans of the buildings and special inquiries indicated in subsequent sections.

We think it probable that, under the special circumstances of the case, if the maps and plans above referred to cannot be prepared for publication in Egypt, application to the Board of Agriculture might secure their multiplication and reduction by the Ordnance Survey. Such a course would secure perfect reproduction and a great economy.

We propose that illustrations, other than plans, should be based on photographs, to be subsequently processed in printer's ink. This would secure permanency and great economy and avoid all the expenses of hand illustration, which alone was available in the expeditions of 1789 and 1844.

We also suggest that a non-commissioned officer of the Royal Engineers, who has passed through the photographic school at Chatham, should be attached to one of the companies of Royal Engineers stationed in Egypt, and be employed in obtaining the photographs.

B.—TOPOGRAPHY.

The general survey of the region may possibly be based on the engineer's map, and plotted on a scale of 100000.

All special sites should be specially surveyed on a scale of 10000, giving precedence to the districts and buildings below the contour of 118 mètres R. L. These sites may be classified

as follows:—1. Temple fields. 2. Forts. 3. Old cemeteries, including circles, &c.* 4. Groups of rock tombs. 5. Old towns and prehistoric sites. 6. Mounds. Magnetic variation to be astronomically determined at each site, and true (astronomical) north to be shown on every map. Contours to be given, say to 3 mètres.

C.—PRELIMINARY RECONNAISSANCE.

First Stage.

It is suggested that the complete detailed survey may be preceded by the undermentioned inquiries. 1. A contour line at R. L. 118 should be shown on the general topographical map. 2. All sites likely to be occupied by cultivation or dwellings should be noted. 3. The feasibility of placing cofferdams or earthen embankments round buildings liable only to slight flooding should be considered. 4. Noting extent of cemeteries. 5. Cataloguing graffiti that will be flooded.

Second Stage.

1. Detailed mapping of sites, plans of temples, &c. (see D). 2. Photographs of all visible inscriptions. 3. Obtaining levelled height of each temple floor above Nile water at some stated date (so as to compare with Aswân and Halfa gauges). 4. Obtaining proper names in the Nuba dialect of every site. 5. Examine, plan and level all the ancient training spurs on the river banks. 6. Note all evidence of the Nile having been at a different level in historic times. 7. Search for all stages of graffiti, &c., near the river level, and all that are dateable, with record of what can be reached on foot or otherwise.

D.—SUBSEQUENT LOCAL INVESTIGATIONS.

Plans, &c.

Plans, sections and elevations of buildings may be plotted to a scale of $\frac{1}{100}$. General plans of a group of buildings may be plotted to a scale of $\frac{1}{400}$. The buildings may be classified as follows:—1. Temples with temenos walls. 2. Walls of and structures in forts. 3. Special parts and buildings of towns and prehistoric sites. 4. Tombs and rock tombs. 5. Churches and monasteries. The true (astronomical) north to be shown on each plan.

E.—WORK TO BE DONE IN EACH TEMPLE.

a. Foundations and Architecture.

Fallen stones to be examined before removal for the purpose of noting which part of the building, whether roof or walls, they came from; and how the fallen parts were constructed—the material, the jointing-dowels. Clear the sand or débris sufficiently to secure a plan complete in every respect. The position of everything found to be shown on plan. Amplitude of temple axis. Elevation of horizon as seen along axis. Search for crypts. Order and date of various parts of the structures, especially of the foundation deposits and of the successive foundations, showing all straight joints, alterations, additions. Methods of construction, nature of material, average dimensions of stones. Pavements, with all marks and indications thereon. All alterations in pylons to be noted. Photographs of all architectural features of importance.

b. Sculptures and Inscriptions.

Photographs of all sculptures and inscriptions, whether on standing or fallen parts, to be made to scale. The position of all such sculptures and inscriptions to be shown on key plans, elevations and sections. Squeezes to be taken wherever possible, to assist the photographic record. Stamps on bricks to be recorded. Graffiti.

c. Colours.

Vehicle. Traces of gilding. Notes of Coptic painting. Colour.—State whether on sculpture or on unsculptured walls, whether on plaster, whether drawn only, and not finished.

d. Pottery and other Objects.

These are to be collected and sent to museum after careful descriptions have been made.

F.—WORK TO BE DONE IN EACH FORT.

a. Foundations and Architecture.

Turn over all soil inside and around. Fallen masses of débris to be examined so that the position they occupied and their relation to the still standing walls may, if possible, be ascertained. Clear sand and débris sufficiently to secure a plan complete in every respect. The position of everything found to be shown on the plans. Observe method of construction, nature of materials, dimensions of bricks, methods of laying, whether with reeds between each or several courses, whether made with or without straw, whether the courses are laid level or undulating, or sloping with the fall of the ground, methods of bonding (if any), bond timber, holes through walls, state and condition of wall faces, and method of bond as shown

on wall faces. Order and date of various parts of the structure, showing all straight joints, additions and varieties of brickwork. Note exact position of foundation deposits, manner of approach to the wall tops, ramps, stairs. Gateways, whether stone lined. Any signs of communications. Plan of structures of whatever nature within the walls, notes of brickwork, stone-work of these structures. Plan of any structure other than modern houses around the outside. Ditches, outworks, paths or roads, wells.

b. Sculptures and Inscriptions. c. Colours. d. Pottery and other objects.

G.—WORK TO BE DONE IN EACH ANCIENT TOWN.

a. Foundations and Architecture.

Plan of town, with its relation to the Nile and surrounding valleys, roads, or forts. Walls (see instructions with regard to walls of forts). Gates (see instructions as above). Whether any part of town is artificially raised, or mounds, or substructures. The nature of these. Houses.—Observe their construction and dates of brickwork, whether all of stone, all of brick or partly of stone and partly of brick. Methods of constructing vaults. Streets. Public buildings. Temples. Churches. Mosques.—Observe their methods of construction, whether altered to suit purposes other than those for which they were first built. Houses.

b. Sculptures and Inscriptions. c. Colours (if any). d. Pottery and other Objects.

H.—WORK TO BE DONE IN EACH ANCIENT CEMETERY.

a. Architecture, &c.

Only a limited number of the most typical stone or brick built tombs to be dealt with. Description of different structures, with plans, elevations and sections. Materials. Plan made of every grave opened, showing the position of everything found in it. Strict marking and separate packing of objects of each group or tomb uncovered. Method of burial: whether mummied or more simple method.

b. Inscriptions. c. Colours. d. Pottery.

Description of everything found within. Photographs and drawings of most important objects.

K.—ANTHROPOLOGICAL AND ETHNOLOGICAL INQUIRIES.

ARCHÆOLOGY IN YARMOUTH.

THE annual meeting of the local Archæological Society was held last week in the Town Hall of Yarmouth. The Mayor presided, and said the Society held a very honourable position. In that old town they had many interesting records of the past, and it was most valuable that there should be a Society of this kind not only to look after these records and to take care of ancient remains, but also to call public attention to them. It was a Society with which the townspeople should be in touch, and he was glad to have been a member for some years. He wished to call attention to the fact that another portion of the interesting Greyfriars' Monastery had lately been secured. Five hundred pounds was now required to preserve this relic of the past. He could not but acknowledge the efforts of their indefatigable local secretary, Mr F. D. Palmer, who had thrown great zeal into the work, and ever took the liveliest interest in their old town.

The *Norwich Mercury* gives the following account of the proceedings:—The Hon. Secretary presented the report for 1894, which stated that visits were paid in the summer to Halesworth and the district, and also to Langley Abbey and other places on the Yare. In September last an opportunity offered for the purchase of a further part of Greyfriars' Cloisters, of which the Tolhouse trustees availed themselves and were now appealing for funds for this purpose. Mr S. Lucas, A.R.A., had written an interesting article on these remains. The action taken by the Society in regard to a museum had resulted in the Corporation undertaking a scheme, and it was hoped that a building now being erected in the rear of the great hall of the Tolhouse would be opened and dedicated to the public at an early date. During the year 3,040 visitors paid entrance fees to the Tolhouse, and 1,190 copies of the guide were sold. The committee maintained its numbers, and there were now 100 members. The balance-sheet showed the year was commenced with 7*l.* 1*s.* 9*d.* in hand, and ended with 6*l.* 10*s.* 3*d.* on the credit side. The Tolhouse account balanced itself within 18*s.* 1*d.* There was no need for the Society to have large funds, and it only needed to pay its way. So far as possible the subscriptions were used in connection with the Society.

The Hon. Secretary said that the paper he read last year on the parish of Eccles was to be reproduced by the parent Society. They were all very sorry to see that the old landmark had been swept away.

Mr. Carter said some ancient papers had been presented by Mr. Goldwin, of Colchester, and on the back of one of these he found specimens of early shorthand, dated 1681.

* There must be large cemeteries buried underground in the neighbourhood of the temples and great towns; these ought also to be sought for and excavated.

Preservation of Ancient Documents.

Dr. Duckett said that there were some very ancient documents in the town, which were built up in the old Guildhall in the churchyard for some 300 or 400 years. People had no notion of their great age. The oldest dated back to 1292, and a great many of them went back to 1300 and 1400. They were in the possession of the Corporation, and it would confer a great benefit if they could be translated and printed. He therefore moved, "That this Society trusts the Corporation may in the near future direct that its ancient leet rolls be published in a similar form to those recently dealt with by the Corporation of Nottingham."

Mr. E. T. Ayers, who seconded, hoped that all the historical documents in the borough would be included. He was informed on the best authority that in the possession of the Corporation there were ancient records of which they were ignorant. The Clerk of the Peace had some very ancient records in his office, and he would like to see all these preserved before they perished.

Dr. Duckett accepted the addendum, and the resolution was passed.

The Hon. Secretary announced that he had received from Colchester two charters, dated 1200 and 1500, with very fine seals attached, which were in excellent preservation. One referred to the appointment of attorneys, and the other related to some land.

Yarmouth Leet Rolls.

The Rev. W. Hudson, F.S.A. (Norwich), read a paper on "Yarmouth Leet Rolls." He said the earliest roll of the Leet Courts of Yarmouth was dated 1366. The term "leet" was used in very early times in East Anglia to denote divisions of a town such as were now called wards, but properly it was a division of a hundred. In Norman times there seemed to have been a tendency to such divisions. It appeared to him that these leet divisions were not of early date, as they described artificial and not natural divisions. Four leet courts were held in Yarmouth—the North Leet, held on June 1; the North Middle Leet on the same day; the South Middle Leet on June 22; and the South Leet on June 23. In the leet rolls no specific days were mentioned, but they only set forth that the courts were held so many days after certain religious feasts. Each leet court had its own jury of presentment, twelve in number, called capital pledges. Some of the offences dealt with were described by the reader. Amongst them were raising the hue and cry without sufficient cause, breaking the assize of beer—that was, selling it at a higher price than that fixed by the bailiffs. Three cases of infringement of the market laws were interesting. One was forestalling of goods on their way to the market for the purpose of selling them at an increased price; forebarring, that was forestalling of goods outside to sell them elsewhere, and not in the local market at all; and regrating, or buying goods in large quantities in the market and retailing them in smaller quantities at higher prices. Another offence was following two trades at once. He found millers fined for being bakers as well, and drapers punished for being tailors also. The system, he said, was fairly tried, and died a natural death from its ineffectiveness. Examining one roll, he found that men were punished for removing goods from ships by night, and thus defrauding the bailiffs of their customs. He also found mention of regulation of the size of nets to be used by fishermen. The fines were assessed by some of the capital pledges. One of the fines he found was 6d. for causing blood to flow from a man until his life was despaired of. The whole system was very much suggestive of the game of forfeits, in which every one paid something, and no one was the worse for the process. One roll, dated 1380, he found to contain a record of the ships arriving, the ports they came from, the cargoes they brought, and the dues they paid. He urged that some of the members should devote a little labour to translating and reproducing some of these rolls.

The Mayor said they were much obliged to Mr. Hudson for his very interesting paper, which cast a good deal of light upon the ways of our forefathers. When the whole of these rolls were translated, he thought much interesting reading would be forthcoming.

Dutch Remembrances in Yarmouth.

Mr. R. H. Teasdel next read a paper on "The Dutch in the District." During the late summer some extensive repairs were effected in the South Pier at Gorleston, and from the soil used for filling the inside of the work a fragment of Dutch pottery was unearthed, bearing the date 1592. Probably what struck the travelled visitor to Yarmouth most was its foreign and Dutch-like aspect, doubtless more conspicuous 100 years ago than now. Evidences of Dutch taste were then exhibited in the cleanliness of the streets, the many flower gardens with wooden summer-houses, the quaint porches attached to the houses, the flat-topped limes, the Dutch clinkers, the posts and chains in front of the houses, the mirrors or reflectors outside

the windows, appropriately called "espions," and the hooks on the walls for the suspension of tapestry on high days and holidays. Much had gone, but much remained. The South Quay had been likened to the Bempjee at Rotterdam, and there were further points of resemblance in the quaint old red brick gables in the rows, the frequent Dutch tiles on the older houses, and the incised slabs with armorial bearings in the parish church. It was probable that this district, which much resembled Holland, owed its system of drainage to Dutch experts, while many of the terms used in marsh farming here were said to be borrowed from the Dutch. From an early period Dutch fishermen frequented Yarmouth during the Free Fair. In the reign of Henry III. an inundation of the Low Countries drove to England a large number of Dutch artisans, and many settled at Yarmouth. Edward III. greatly encouraged these immigrants for the sake of their skill in cloth manufacture. Philip II. also drove over numbers of Dutch and Flemish Protestants, 300 of whom settled in Yarmouth and taught the inhabitants to prepare, pack and brand herrings in the Dutch fashion, greatly to the advantage of the port. In 1586 Queen Elizabeth granted them permission to dwell in the town and pursue their avocations, but jealousies arose, and in 1574 the Corporation imposed stringent restrictions upon the settlers. In 1569 an attempt was made to expel them, a conspiracy being hatched at Norwich; but it was detected, and its leader and two others hanged. St. Bartholomew's Massacre in 1572 increased the number of Dutch and French refugees, and the Revocation of the Edict of Nantes brought a fresh arrival. The building now occupied on the South Quay by the Public Library was granted the Dutch by the Corporation as a place of worship, but they were required to keep in repair a clock on the face of the building. It was called the Dutch chapel, and so occupied until 1681, when owing to the war with Holland the last of the once numerous colony left Yarmouth never to return. The Sunday before Michaelmas Day was called the Dutch Sunday. During the day there was considerable traffic in pipes, Dutch toys, ginger-bread and "Domino clumps." In the evening the Dutch fishermen paraded the town shouting songs, and next day went to sea. It was the custom for the Dutch and Flemings to be hired by Yarmouth merchants for the fisheries, and their influence on the language was shown in our sea terms of sloop, schooner, yacht, boom, skipper, taffrail, which were still employed as Dutch. It was also stated that a Yarmouth sailor would have no difficulty in making himself understood in Antwerp and Rotterdam. Mr. Teasdel also referred to the construction of the present harbour by a Dutch engineer, Joar Johnson, who was paid at the rate of 4s. a day for his services.

At this point an adjournment was made to the entrance hall, where was a loaded refreshment buffet, evidence of the hospitality of the hon. secretary. The members, returning to the committee-room, inspected there several curious old stones, pieces of pottery, tiles, &c., found since the high tides at Gorleston. One stone showed traces of beautiful carving, and was no doubt a piece of one of the old Gorleston churches, for much material from them was used in making the present haven.

A paper was next contributed by Mr. E. T. Ayers on

Norfolk Field and Place Names.

The names and appellations of fields, roads, streams and particular areas and localities in England contain veritable mines of historical and traditional information of an interesting and instructive character. This information was to a very considerable extent hidden from general notice and observation, because many ancient designations had ceased to be in common use in their original sense, and the meanings of many had been entirely lost. Bearing in mind the various migrations and invasions, it was possible by a little attention and industry to arrive with tolerable certainty at the purport and meaning of most of these names. In every community it was a matter of necessary convenience that distinctive names should be given to places, and those names would naturally in early times be given with some correspondence to the situation and character, whether high, low, level, or uneven, the nature or products of the soil, neighbourhood to the dwellings of man, rivers, &c. Accordingly in Norfolk he found in the names of localities, fields, roads and streams traces of (1) the ancient Celtic or primitive British language which was in use before the Roman conquest and the Anglo-Saxon invasions; (2) the Roman or Latin language; (3) the languages of the Angles, Jutes and Saxons; (4) the languages of the Danes, Swedes and Norwegians; and (5) the Norman French language. The primitive British or present Welsh language as a spoken language seemed to have been almost completely driven out of England. The Romans having made no attempt to colonise, few traces were left of the Roman or Latin language. The Anglo-Saxons and their allies, however, came over in vast numbers and really settled here, and their language obtained a wide and firm footing, becoming substantially the language of the country. The Danes followed their example, and considerable additions were

therefore made from the Danish, particularly in the seaboard counties of Eastern England, where they chiefly settled. Then the Normans enforced the use of the French language for 350 years, and thus added much more to our language. It was remarkable, however, that Anglo-Saxon continued to be employed in our homelier and more familiar ideas. Mr. Nall had pointed out that the names of almost every hamlet in the hundreds of East and West Flegg (Norse *flegg*, Danish *vlak*, flat), lying near Yarmouth, which were the most important of Danish settlements, were of Norse derivation, compounded of some common Danish personal name, and the suffix "by," such as Billockby, Clippeby. Other place names, by their terminations of ley, land, thorp or thorp, gan, toh or tone, strand, &c., showed their Danish origin. Mr. Ayers then quoted numbers of illustrative instances. The ruggedness of the Danish place names was remarkable, and they had the advantage of varying very distinctly from each other in sound, as Hemsby, Ormesby, Scratby, Oby and Billockby. So it was with most of the 512 Danish "bys" or "byes" in England. He found 90 instances of by, bi or bye in Denmark, 58 in Sweden and Norway, nearly all in Sweden. The uncommon names of Gambleby (in Cumberland) and Oby (in Norfolk) had their exact counterparts, and he also noticed Hycklinge, Bure, Horning and Stalheim, while names ending in tof, toft, vik or wick, dal, an, torp, darf, holm, fjeld, fjord, ham or hamm frequently occur. In Finland there were five "byes" near the shores of the Gulf of Bothnia. Names ending in en or em were frequent in Belgium, but no by or bye, and he did not find any in North Germany, and only one by and one bye in France. A writer in "Chambers's Journal" had pointed out that the names of rivers almost without exception denoted a great variety of qualities, smooth, rough, winding, sluggish, &c. Of the names which the Romans imposed there were exceedingly few traces, the most obvious being those in which the word chester or carter, from castra, a camp, were found. The names of places of Anglo-Saxon origin were seldom descriptive of sites or qualities, and very generally composed of the name of the original founder or proprietor in a corrupted form, with the addition of wick, burgh, thwaite, ham, ton or tun. Haddington was the place of residence of Haden, and Edinburgh the fortified settlement of Edwin, both Anglo-Saxon chiefs. In some instances the names were composed partly of Celtic and partly of Saxon or Danish terms, the one being grafted on the other by the succeeding races. Mr. Ayers then quoted typical words in illustration of his paper, particularly some of Celtic origin of great antiquity and still in use here, almost unchanged in form and meaning since the days when the aboriginal Britons roamed over this island.

OLD TORONTO BUILDERS.

A CORRESPONDENT of the *Canadian Architect* writes:—The dead past has not much interest to many whose lot is with the living present. As Artemus Ward has remarked, however, there is a pleasure in reminiscences of olden times, whilst Professor Wrong, of the Toronto University, in his lecture of a few days ago, is doubtless right when he says that many mistakes of the present would be avoided if people were better acquainted with the history of the past. "History is philosophy, teaching by examples," as another writer has said.

Though untempted to delve deep into the buried past there are few who have not an interest in that particular past which relates to their own selves or their individual callings. This has been the thought of the writer, as he has allowed memory and historical incident and data to take him back to the days when Toronto was best known as Muddy York, and the magnificent buildings which are the pride of her citizens to-day were unknown.

To make a start at the beginning of the century, there came to York in 1800 Caleb Humphrey, a carpenter, builder and contractor. He was one of the pew-holders of St. James's Church from its commencement in 1803, and pioneers whose memories will enable them to locate the south-west corner of Toronto and Adelaide Streets, as it existed in those days, will remember Caleb Humphrey's house. More strictly speaking, the late John G. Howard, to whom the city owes a debt of gratitude for his handsome gift of High Park, ranks as an architect rather than a builder, and yet many of the early houses of Toronto were built by him. The first 11-inch plank side-walk on King Street was laid by Mr. Howard. He designed the spire on St. Paul's Church, Yorkville, in 1841, the work on which was performed by Mr. John Ritchey, the framing by Mr. Wetherald, and the raising was superintended by Mr. Joseph Hill. This was one of the curiosities of the time, and received significant mention in Dr. Scadding's "Toronto of Old."

A list of the inhabitants of York in 1805 includes in its numbers William Cooper, a builder, and owner of one of the first wharves and warehouses in York. Collin Drummond was

a builder and owner of a lumber-yard located in Yonge Street, between Wilton Avenue and Shuter Streets, the burning of which, with other properties, is still fresh among the boyhood memories of the writer. Henry Hales was a builder and contractor of the first decade of 1800. He had a brickyard at the south-east corner of Duke and George Streets. William Smith was a builder who came to York with Governor Simcoe, and was the first man to take up a building lot after the laying out of the town plot. This was located at the north-east corner of King and Sherbourne Streets, and the house which he built is still standing there. William Smith, jun., was a son and a builder. The boys of Toronto, who on Saturdays tramped out Yonge Street to Hogg's Hollow, remember well the Severn brewery in Yonge Street. This building was originally built by the father of the present John Baxter.

The recent burning of the new Globe building brings to memory the old Globe building, from which was published that journal when some of us were boys in our teens. It was familiarly known as Dallas's building, and was situated on the property where now stands the Canadian Bank of Commerce. Let us go back, however, to the days when the printing-press performed its mission on that site, and it will be remembered as the spot where stood in 1818 the first Methodist church at York. This remained a place of worship until 1833, when it was converted into a theatre. A memento of this church building is to be seen in a walking stick made from a portion of the altar rail by one who in those days was known as "Old Daddy Petch," and which later came into the possession of Mr. Robert Carroll, one of the best known contractors of the present day. Mr. Petch built the old church in question, and at one time was a partner of ex-Mayor Manning. By the way, I am reminded that Mr. Carroll is to the manner born, being of the fifth generation of builders bearing the name of Carroll. The history of the Globe corner of later days is well known. The old buildings were afterwards supplanted by the fine ware-rooms of Jakes & Hay, furniture manufacturers, to take their place later by the Bank of Commerce.

The firm of Metcalfe, Forbes & Co., or as they were sometimes known, The Company, were builders of the old Bay Street Presbyterian church, situated on the corner of Richmond and Bay Streets, and of which the Rev. John Jennings, D.D., was for many years pastor. John Ross Robertson, in his "Land Marks of Toronto," tells the story that early in the sixties a great storm occurred in Toronto, and one of the stone pinnacles at the south-east corner of the church was blown down and fell through the roof. The stone in its flight downward detached a piece of wood with a nail in it, which also fell, the nail piercing a Testament in one of the pews and puncturing the book through to the text, Matt. vii. 25, "And the winds blew and beat upon that house; and it fell not, for it was founded upon a rock." The firm of Metcalfe, Forbes & Co. were also contractors for Trinity College and other prominent buildings. James Metcalfe, of this firm, was well known to many as California Metcalfe, from the fact that he went off to that country and returned to Toronto a rich man, having struck it right in the gold diggings or elsewhere.

Messrs. Ewart & Parkes and Mr. Joseph Turton are known as the contractors of the old Parliament buildings. McDonald & Young make claim of having built the present city hall in 1845. The College Avenue of a quarter of a century ago was different from the College Avenue of to-day, and was a favourite excursioning point for the boys of that time. I can well remember the spot known as Sleepy Hollow, the residence of the Hon. John Beverley Robinson. This well-known residence was built by Mr. George Shaw, father of Alderman Shaw, and was the first building he ever put up.

The contractor for the masonry-work of Knox Church, Mr. J. Grant, was a familiar figure in building circles more than twenty-five years ago. He was known as Tam O'Shanter, because in addition to his business as a contractor he kept a tavern near Duchess Street, to which he had given this name. The carpenter-work of Knox Church was done by McBean & Withrow, the latter the father of the present John Withrow. The gas office, the building of the Trust and Loan Company, and other commercial buildings, were erected by A. Burrows, who was a contractor of prominence in Toronto thirty years ago. John Plenderleith's carpenter shop on the corner of Elizabeth and Edward Streets, taking in the larger part of a square, gave employment to many men in the trade, who are still to be met on the streets of Toronto. An old builder of those days, who keeps active in the service despite advancing years, is Mr. W. J. Hughes, a resident of Simcoe Street. He came to Canada in 1832. It may have been forgotten by many citizens that Mr. James Dobson, late postmaster at Yorkville, who died at the age of eighty-five years in December last, was a carpenter, and carried on building operations in the city for a number of years.

One of the best-known builders of more recent years, and yet an old-timer, was Mr. John Ritchey, who built Ritchey's Terrace, a row of houses in Adelaide Street, between Bay and York Streets, some of which are still standing, though ancient-

looking. He was born in 1796 and came to Canada from Belfast, Ireland, in 1819. He died April 30, 1866. He built St. George's Church, St. James's Cathedral, twice, before and after the fire; Judge Haggarty's residence, Simcoe Street; the old Lyceum for French in King Street W; the Dominion Express Company's offices, Yonge Street, and his last work was the Dilworth House in Jamieson Avenue. There are a few men in the building trades to-day who remember John Ritchey, and his name suggests to them interesting incidents in the methods employed by contractors in the olden days.

No sketch of the old builders of Toronto would be complete without a reference to John Harper, father of George Harper, a well-known Toronto architect of to-day. John Harper was a son of Richard Harper, who left Belfast, Ireland, for New York in 1810. The father remained a resident of that city until 1817, when the family removed to Toronto, and Mr. Richard Harper entered into the building business. John Harper, the son, followed the father's calling and built St. Michael's Cathedral, Trinity Square; the first general hospital, the first Toronto observatory and laid the foundation of the present asylum buildings. He also built what is now known as the Newsboys' Home, a building intended at that time for the Canada Company's offices. The first depôt of the Northern Railway was his work. John B. Smith, founder of the firm of J. B. Smith & Sons, lumber merchants, Toronto, and who died in March last, was a contractor rather than a lumber merchant in his early business days.

This much about old Toronto builders. The story is by no means exhausted. The digging process is an interesting one and much more could easily be unearthed.

THE PAINTINGS AT POMPEII.

IN a letter to the *Standard*, Mr. Fitzgerald Marriott, writing from Sorrento, says:—

I regret to say that during my long and thorough acquaintance with Pompeii I have come to the conclusion that it is not only the Harrys of Naples who spoil the frescoes with their autographs, but it is the English, American and German tourists who on free days collect quantities of mosaic and tear off pieces of fresco; and this not from places where it can be spared, but from walls and floors that are merely falling into decay, and need care rather than spoliation. At the *table d'hôte* in the Hôtel Suisse, and also at the Hôtel del Sole, I have frequently heard one tourist ask another how much mosaic he had managed to tear up. I have also seen the copyist of the pictures—a common fellow, employed to make tracings and copy in the colouring of the largest frescoes for the Naples Museum—scrape off with a knife small pieces of loose fresco paint in the House of the Wounded Adonis, utterly indifferent to the result. The walls in Pompeii used to be waxed, and this is the cause of the fine gloss on many of those seen by Mr. H. A. Kennedy; but owing to lack of funds and their misappropriation by certain officials this had to be given up, but I trust to see it soon commenced once more, as this waxing process is the only means of preserving the surface and the colour from the effects of damp and heat. I cannot agree with Mr. Kennedy altogether; he has quite overlooked the examples of the third style of wall-painting, which are the most delicate of all; the best example, alas! much faded, of the "Candelabrum" variety is in a room in the Casa del Centenario, that has a *solarium* on its threshold and is next but one to the locked-up room in that house. The finest example of the "Egyptian" variety is in the house of Cecilius Jucundus, in the *tablinum*; and others are in the Casa del Orfeo, and in the house in Regione IX., Isola 5, No. 18.

Mr. Kennedy's criticism of what Neapolitan taste values is very true—the authorities prefer all that is large and brilliant, not always that which is in good taste. One word I would like to add about the house of Siricus. He says, "The painted architectural intervals . . . stand upon basal panels composed of a harmony in yellows, rich, pale and reddish. They contain landscape subjects, touched in with the most airy lightness and delicately framed." Had Mr. Kennedy seen these some years earlier, or studied the contents of these and similar little round or square pictures for some years, he would have seen that they were pictures of houses and farmhouse scenes, from which much can be gathered of the general form of old Pompeian houses, both in and without the town. Those in the house of Siricus are about a foot square, and are much obliterated; there were six of them. For similar small pictures of houses see Gell's "Pompeiana" and the French edition, "Vues des Ruines de Pompei," p. 132.

I regret to differ also with regard to the woman in the picture of the *Drunken Hercules* in the *Exedra*; instead of Dejanira, she appears more likely to have been intended for Omphale, the Queen of Lydia, for love of whom Hercules

surrendered his lion's skin and club; Bacchus, with Fauns and Bacchantes, is represented in the upper portion of the picture laughing at the evident result of his wine, the moral being that strength becomes folly and weakness with over indulgence. Had the female figure been Dejanira, the wife of Hercules, there had been no reason to represent him as drunk (see "Notes on a Few Houses" in our "Facts about Pompeii"). I must differ also from Mr. Kennedy in that all artists and students of importance whom I have ever met at Pompeii have always known the room in the Casa della Regina Margherita. Moreover, the guide-book "Baedeker," and I have no doubt also Murray, does mention it, so does Rolfe's "Pompeii;" a figure in the picture of *Narcissus* in this room used to have a club under its arm; it has become obliterated, but it has made me consider that the painting combined the story of Narcissus and his reflection with that of Hylas (the attendant of Hercules) and the jealous nymphs.

But I can fully endorse the remark that the authorities seem to think that further excavation is more popular than immediate preservation, or even than the completion of the excavation of the five-storeyed houses in Regione VIII.; and in the meanwhile they are wasting time and money to please an unappreciative Neapolitan population, little thinking that Englishmen, whether simply tourists or students of archaeology like myself, can appreciate what is truly interesting and already find in Pompeii quite sufficient to study.

GENERAL.

The Sales of pictures from the last exhibition of the Glasgow Institute of Fine Arts amounted to 3,378*l.*, an excess of 15*l.* beyond the sales of the preceding year.

The Exhibition of the Dudley Gallery Art Society will open on Monday next. To-morrow there will be a private view.

Archdeacon Sheringham, treasurer of Gloucester Cathedral Restoration Fund, announces that 1,335*l.* has been subscribed for the special Lady Chapel Fund. To complete the work another 800*l.* is needed.

The Report of the improvements committee of the London County Council, which recommended the construction of a roadway from Whitechapel to Tower Bridge, was rejected on Tuesday.

"Lanigans Folly," a tower which stood on the mountainous ground near Borrisoleigh, co. Tipperary, succumbed during the late gale. It was a costly and useless structure, and as it was built on sand there is surprise it endured so long.

Mr. W. Kaye Parry, M.A., has been appointed by the Board of Trinity College, Dublin, examiner in practical sanitary engineering for the qualification of State medicine in the University of Dublin.

Mr. Leonard Stokes will read a paper on "Observation" at the meeting of the Liverpool Architectural Society, on Monday, the 11th inst.

Mr. Alan S. Cole will deliver the first of the series of Cantor lectures at the Society of Arts on Monday, the 11th inst., on "Means for verifying Ancient Embroideries and Laces."

Mr. Norman Macleod, who was for several years secretary to the Science and Art Department, died in Paris on Tuesday in his eighty-second year.

Mr. Arthur Blomfield Jackson has been appointed a surveyor under the Ecclesiastical Dilapidations Act to the diocese of St. Albans.

The French Minister of Education, on Wednesday, applied for a further grant of 150,000 francs towards the expenses of the excavations at Delphi, which are in charge of the French School at Athens.

The Arts Committee of the Walker Art Gallery, Liverpool, have received a letter from Messrs. Walter and Stanley Russell, executors of the late Mr. T. R. Russell, offering to present to the gallery, in memory of their late father, the life-sized marble figure entitled *Fate-led*, by Mr. Albert Toft.

The Paisley Art Institute Exhibition was closed on Saturday. Fifty-four paintings have been disposed of and a sum of 338*l.* realised.

Mr. Abraham Mosley, of Northampton, has been appointed surveyor to the Finedon Urban District Council.

A Picture by Mr. T. Y. Titcombe, *Primitive Methodists*, which obtained a prize at the Chicago Exhibition, has been presented by Messrs. Grainger & Smith, of Dudley, to the local art gallery.

The Institution of Civil Engineers will meet on Tuesday, the 12th inst., when the discussion will be resumed on Mr. J. Richardson's paper, "The Mechanical and Electrical Regulation of Steam Engines."

The Architect.

THE WEEK.

THE death of M. JEAN PORTAELS is a great loss for Belgian art. As he was born in 1818, he had exceeded the three-score and ten limit, but he was so hale and hearty a gentleman he seemed likely to be competent to paint and to direct the Brussels Academy for several years to come. When we illustrated some of his works we said that one of his pictures was known to every visitor to Brussels. We referred to the fresco which fills the pediment of the church in the Place Royale. After forty years of exposure to the weather it is still most brilliant. M. PORTAELS was born in Vilvorde, Brabant, in 1818. He studied under the Belgian-master NAVEZ, and afterwards he went to Paris and worked with PAUL DELAROCHE. M. PORTAELS spent several years in Rome, and then, like so many of his contemporaries, he was attracted to Egypt. From that country and the eastern part of Europe he derived many of his subjects. He hated the commonplace, and the Bulgarians, Slaves and kindred races secured his preference. Tragic scenes were often painted by him, such as *The Suicide of Judas*. Some of his paintings are to be seen in Belgian churches. As director of the Brussels Academy, M. PORTAELS exercised much influence. He never set up his own manner of treatment for the imitation of students. His aim was to encourage individuality as much as possible, and the number of excellent painters who were trained under him is the best evidence of his success.

THE members of the Glasgow Town Council do not appear to be doing themselves much credit by the reasons they give for raising an outcry against the publication of tenders for municipal works. They maintain that as in consequence of the appearance in the newspapers of the tenders for the tidal weir on the Clyde, the firm of contractors who stood lowest withdrew their offer, Glasgow has lost more than 4,000*l*. There is another aspect of the case which they have neglected to consider. Is it worthy of a great city like Glasgow to endeavour to have work executed at a price which would involve the contractors in a loss of over 4,000*l*? By one of those oversights which are common enough when tenders are being made up in a hurry, some items relating to the weir were omitted or undervalued. The error was perceived when the tenders were published, and the contractors prudently, and as they were entitled, endeavoured to save themselves from the consequences of a clerical error. That is only a petty way of dealing which tries to gain profit by obtaining things at less than their value, and which is indifferent to the losses of vendors. Glasgow did not, we hope, gain its position by commercial morality of that sort, and it is to be regretted that such laxity of principle should now prevail in any body of the citizens. It is, however, remarkable that the objection to the publication of tenders always arises from unfairness of some kind. At one time, as in Glasgow, there is a desire to take advantage of an error in calculation; at another time it is intended to assert that a building cost a sum which would not correspond with the tenders; or it may be there is a desire to conceal the fact that an excessive amount was expended on construction. Whatever may be the cause assigned, the object of the concealment means wrong to somebody. People who have a concern in the erection of buildings or the construction of engineering works, should know that publicity of tenders is nowadays the best guarantee for honest dealing, and intending purchasers of new buildings should always hesitate when they find (if there was competition for the work) that the tenders have been dealt with in a hugger-mugger way.

A RULE *nisi* was granted on Tuesday which will probably have eventually the effect of determining an important point in connection with the payment of district surveyors' fees. In the West Hackney district a row of fourteen houses was nearly completed when the builder became bankrupt. The work was taken up by another builder, and when the houses were finished the surveyor applied to him for the fees. He

declined to pay, on the ground that it was his predecessor who was liable, whereupon he was summoned. The magistrate of the South London Police Court dismissed the summons and refused to state a case. In applying for a rule which would oblige the magistrate to state a case, it was contended that *TUBEZ v. GOOD* which he relied on was not applicable. In that action the buildings had been completely roofed in, and the district surveyor had tried to get his fees from the owner when the buildings were fully finished. But in the present case, at the time when the first builder became bankrupt, some of the buildings were not completed and not covered in, and so the second builder was assumed to be liable for the fees. Although they may not have many friends, it is only fair that district surveyors should receive the fees to which they are entitled. As long as it is not possible to demand fees until fourteen days have elapsed after the roofing of a building, the builder for the time being would appear to have assumed the responsibility for the payment imposed by the Act. Under the new Act, in case of failure the surveyor can obtain his fees from the owner or occupier.

AT the last meeting of the Sunderland Guardians the house committee specially recommended:—That the plans of the proposed new infirmary as prepared by the architect be approved; that the front administration block, two pavilions, corridors, maternity pavilion, probationary pavilion, laundry and boiler-house and mortuary be erected (leaving the kitchen and staff apartments on male and female side to be erected at some future time), at the estimated cost of 34,725*l*.; that application be made to the Local Government Board for power to borrow a sum not exceeding 35,000*l*., to be repaid in thirty annual instalments of principal, with the interest on the balance remaining each year. The Chairman explained that, under pressure of the Local Government Board, the Guardians were compelled to erect an infirmary. In the competition the plans of Mr. J. SHIELDS were accepted. They would cost 50,000*l*. to carry out. Owing to the depressed state of trade it was necessary to restrict the expenditure to 35,000*l*. The recommendation was adopted.

ALTHOUGH the French never possessed a painter of more value than WATTEAU, it is remarkable that neither the Louvre nor any of the galleries possesses an adequate number of his works. Still more strange is the absence of any statue of the painter, although men of infinitely inferior interest have their memorials in bronze and marble. Efforts are now making to remove the discredit which arises from the latter cause. A statue of WATTEAU is to be erected in the garden of the Luxembourg. The competition among the sculptors was determined a few days ago. Some of the models had to be set aside on account of their expensiveness. After a long discussion it was decided to select a model submitted by M. GAUQUIÉ, the architectural part being designed by M. H. GUILLAUME.

COMPETITIONS are rare in Ireland, and it is therefore not surprising there is a delay in selecting the design for the proposed lunatic asylum which is to be carried out at Portrane. At the meeting on Tuesday of the governors of the Richmond Lunatic Asylum (for the new buildings will form a country branch of that institution) a letter was read from the Board of Control suggesting a conference with a committee of the governors. The Board of Control also forwarded the report of Messrs. PATTERSON & KEMPSTER, the surveyors employed to prepare estimates of the cost of each of the three designs for the Portrane Asylum, submitted under the names "Aspect," "Luna" and "Mens Sana," which were selected out of all submitted. The Board of Control thought the design marked "Aspect" most suitable. They were, however, not prepared to adopt a plan which would entail an excess of the prescribed sum. The designs also had been declared by the committee of selection to be of equal merit. "Aspect" was by Mr. G. C. ASHLIN, and the surveyors' estimate of the cost of that design was 246,135*l*. The estimate for "Luna" (Messrs. RAWSON CARROLL and BATCHELOR) was 229,910*l*., while that for "Mens Sana" (Mr. KAYE PARRY) was 211,172*l*. It was decided to hold the proposed conference to-morrow.

WHEWELL AND ARCHITECTURE.

IN the course of the century which has elapsed since WILLIAM WHEWELL was born in Brock Street, Lancaster, we doubt if a more versatile man appeared in England. He might be considered as the last of the scholars who could claim to have taken all knowledge for their province. He was Mathematical Lecturer in Cambridge in his twenty-fourth year. Ten years afterwards he was appointed Professor of Mineralogy. Another decade passes, and he becomes Professor of Casuistry. When the Lowndes Professorship of Astronomy was vacant he tried to obtain it, and there were no doubts about his competence. He founded a chair of International Law, and it was understood he intended to be the first occupant. At another time he appeared to be anxious to see himself Professor of Architecture. He served in various offices in the University, and ultimately became Master of Trinity College. Yet with all his labours there was a time when he wished to increase them by taking charge of a parish.

WHEWELL'S writings are no less remarkable for their variety. The story which is told of the graduate who wished to diminish the master's reputation for omniscience by getting up the subject of Chinese music, and after exhibiting his knowledge discovered that he was wholly indebted to WHEWELL'S articles is, like many others of the same sort, a testimony to the belief which was held in Cambridge about WHEWELL'S amazing industry and his interest in everything. The Bridgewater Trustees considered he was the best fitted to write about "Astronomy and General Physics considered with reference to Natural Theology." His "History of the Inductive Sciences" and "Philosophy of the Inductive Sciences" have become classics. Although JOHN STUART MILL was opposed to many of the conclusions, he testified that WHEWELL'S writings are by a man of extraordinary attainments, and eminently serviceable in clearing from confusion the initial steps in the analysis of mental processes. For many WHEWELL'S books on "Moral Philosophy" and "Political Economy" are no less important. Then there are translations of "The Platonic Dialogues," treatises on various branches of mathematics and physical science, translations from the German, poems, sermons, &c. Most of his works were made subjects for discussion, and the replies to opponents occupied much of his time.

For a man who was so active and various in his pursuits, a subject more or less would appear to make little difference, and it might easily be assumed that he cared as little for architecture as for Chinese music. There were reasons which made architecture one of WHEWELL'S pet studies. Primarily it must be granted that early associations were in favour of the art, and especially Gothic art. WHEWELL was the son of a master carpenter. When it was proposed that the boy should be removed from the Blue School to the Grammar School, his father replied, "He knows more about parts of my business than I do, and has a special turn for it." We may therefore assume that young WHEWELL possessed constructive ability. Then we must remember that Lancaster in the early part of the century was a picturesque place. As he once said at a public dinner, "In the drama of my life there are but two scenes, Lancaster and Cambridge, and the early scenes of Lancaster have been enhanced by the transition from one to the other." The parish church and the castle were never long absent from his mind. We may add there was another reason which operated in favour of Gothic. WHEWELL at an early age became one of the dons of his University, and in consequence it was necessary for him to appear in buildings which imposed on him all the inconveniences which belong to the Classic style—a style that was not intended for habitations or for climes where winter reigned, uncontrolled by constitutional checks, as in Britain. What had to be endured was described by WHEWELL in the account of his first appearance as a Moderator:—"The examination is conducted in a building which happens to be a very beautiful one, with a marble floor and a highly ornamented ceiling, and as it is in the model of a Grecian temple, and as temples had no chimneys, and as a stove or a fire of any kind might disfigure the building, we are obliged to take the weather as it

happens to be, and when it is cold we have the full benefit of it." Is it any wonder that, after undergoing privation of the kind, so many Cambridge men should be ready, like MONKBARNES, to suffer any sacrifice so long as Gothic and comfort triumphed? The Senate House in the days when heating by hot water was not much practised was a standing argument against a Classic revival.

But the most potent of all causes in determining WHEWELL'S predilection towards Gothic was that nature had made him a system-monger. In replying to some of Archdeacon HARE'S friendly criticism on his character he once said:—"If you had called me a persevering framer of systems, or had said that in architecture, as in some other matters, by trying to catch the principle of the system I had sometimes been able to judge right of details, I should have recognised some likeness to myself; but what you have said only makes me ashamed." But it was only with objective or external things that he cared to deal. The subjective was his abhorrence. In his early days he wrote:—"A man who is always looking for symptoms in himself will not often be healthful; a man who studies all the motions of all his limbs will not probably be graceful; and a man who is everlastingly watching the operations of his own mind and imagination is not likely to feel or to think freely." For a man who had that sort of belief there could hardly be a more attractive field than Mediæval architecture presented in those days. The history of the art was unknown, for there was no document forthcoming which would throw any light upon the intentions of the designers. Why might not WHEWELL aspire to bring order into chaos? As Professor of Mineralogy he was acquainted with the use which could be made of classification; was it not possible to accomplish a similar work with buildings? He had also a faith that was almost superstitious about the omnipotence of EUCLID and the applicability of a system of axioms, propositions and problems to all things from mechanics to morals. Accordingly he resolved to try his hand on the French churches.

The choice was characteristic. With all his power WHEWELL'S was not an originating mind. He prized his own translations, and much of his scientific and other work was only a sort of translation or paraphrasing on a big scale. In his architectural experiments he leaned on RICKMAN. But RICKMAN had not gone beyond England, and by taking up French cathedrals and churches WHEWELL was therefore appearing as a sort of pioneer. He was safe in having RICKMAN'S guidance, but the English architect was a most modest man, and would never have thought of proposing to himself such "problems" as WHEWELL started with:—

Are there in other countries the same successive styles of Gothic architecture as here, exhibiting the same leading characters, distinguished by the same differences? Are the same great leading characteristics accompanied by the same details and groups of minuter peculiarities? Where the styles come in contact, do they manifest the same transitions, the same mutual accommodations and imitations as with us? And, again, when we look at buildings with reference to their beauty, do the artists in the different countries appear to have been guided by the same principles and the same feelings? Each of the three styles of English Gothic has its peculiar kind of beauty, and probably each has its special votaries who admire the masterpieces of their favourite style as the perfection of the art. Do we find this to be the case elsewhere? And so far as we can detect the supreme aim, the perfect ideal, of the genuine artists of each of the English styles, do we again meet with the same thought, the same purpose, in the great works of successive ages on the Continent? In short, how close or how wide is the analogy which obtains in the principles and history of architecture in different parts of Europe?

His first tour in France was in the summer of 1823 with KENELM DIGBY, the author of the "Broad Stone of Honour," "The Ages of Faith," "Comptum," &c., as companion. They visited Abbeville, Dieppe, Lisieux, Caen, Mont St. Michel and other places in Normandy. According to DIGBY, a table was drawn up by WHEWELL, which displayed the distinguishing features of the styles. In 1825 he visited Germany, ostensibly for the purpose of examining the collections of minerals, but buildings received attention from him. Four years afterwards there was another tour through Germany, and parts of Switzerland and Italy were seen. WHEWELL had an introduction to MÖLLER, the architect, at Darmstadt, who told him how he became possessed of the old drawing of Cologne

Cathedral. The story is worth repeating, in MÖLLER'S words:—

"One morning," he said, "a young man came to me—a painter whom I knew, and offered me some old rolls of parchment, drawings of architecture; he had told me of them before; he described them as drawings of Strasburg Cathedral. I began to unroll the parchment. From a small portion of the lower part, I recognised Cologne. I had before drawn it, and I knew that the original drawings had disappeared. My wife, who was sitting by making coffee, said that I turned quite pale immediately. I told my friend that I should be glad to have his parchments, that I would pay him for them, which he declined. I had them unrolled then, found them what I expected, and was overjoyed. As to the history of the affair, it appears to be this. The treasures of Cologne were saved by being sent to Prague. At the peace of Luneville, the commissioners who were to settle the interests of the confederated States met at Darmstadt at the 'Grape.' All official papers were brought there; and among the rest, it would seem, these Cologne ones. After the arrangement of affairs, the French ambassador, who had the management of these matters, left a quantity of papers and documents, which appeared to him useless, to be disposed of by the waiter at the 'Grape.' Among these was this Cologne drawing. It was stuffed into a granary, was used for some time for drying beans, and might have lain there till now but for an event which brought about an illumination. Parchments were then sought out for transparencies, and among the rest it would seem that my friend, the painter, got possession of this one, which I had from him."

WHEWELL'S acquaintance with RICKMAN probably arose out of consultation over the results of the continental journeys, for in 1830 we hear of the two travelling in Devonshire and Cornwall. WHEWELL'S small book on the French buildings appeared in that year. In 1830 he also visited Yorkshire, and he describes Rivaux Abbey as the most beautiful object he had seen. WHEWELL and RICKMAN in the autumn went on a trip to Normandy. In appearance they were unlike, and from the contrast they excited curiosity. WHEWELL was a big man, and he describes his companion as "a very remarkable figure in his way; he wears the Quaker dress, which of itself would draw some notice, and being a little, round, fat man, with short, thick legs and a large head, he sets off the dress to great advantage. It is a difficulty for me to saunter along as slowly as he walks, and as, besides, he is perpetually running from one side of the street to the other to peep into whatever catches his attention, our motions are very irregular and apparently ill-connected, and we seldom move far without the honour of some special spectators." The two friends were arrested, as a matter of course, but the sight of a business card of RICKMAN'S overcame all the charges which were made, and they were set free. There was one other journey together to see some of the Northamptonshire churches. Afterwards WHEWELL went on his architectural excursions alone.

When WHEWELL went to Cambridge for the first time he was unable to give any account of the buildings, for, said he, "the fact is I am a desperate bungler at putting brick and stone into black and white." With him a difficulty was something to be overcome, and that he was able to treat one of the most difficult of architectural subjects in a lucid way is a testimony to his perseverance. The character of his conclusions was suggested by BOISSERÉE, when he said that WHEWELL too exclusively assumed the vaulting to be the leading principle in the development of Gothic. In every attempt to form a system some feature or principle must be allowed prominence, and while WHEWELL admitted that he might have over-estimated the importance of the vaulting, yet he could claim that by doing so he emphasised relations which exercised a powerful influence on the progress of the art. Sixty years ago people were not clear about Gothic architecture having principles, and the authority of WHEWELL on the subject was important. When he asserted, working, as it were, downwards, that in the style a new principle of connexion came first, and unity followed, "the lines of pressure are made the prominent features; the compound arches are distributed to thin props; the vaults are supported by ribs; the ribs by vaulting shafts; the upright meeting of the end and side is allowed to guide the neighbouring members; finally, the general authority of vertical lines is allowed; the structure is distributed into compartments, according to such lines, each of these being symmetrical in itself; the continuity of upright lines being established, the different planes of decoration glide into tracery and feathering, and the Gothic system is complete,"

WHEWELL was adopting the most effectual language to convince Cambridge graduates. By preferring to take the interiors for study, he treated buildings as organised things and suggested that all parts combined to attain one end. The vaulting became important in WHEWELL'S eyes, not only for its own sake, but because he believed that from the intersections the Pointed arch was suggested. He does not pose as the first to express that theory; any distinction which may belong to it (for he considered the origin of the Pointed arch is only a trifling inquiry) he leaves to SAUNDERS, WARE and KERRICH. But the invention of the Pointed arch in WHEWELL'S opinion was of less importance than the invention of the flying buttress, which enabled a church to become "a coronal upheld by the stony arms which the Christian architects learnt to make powerful and obedient for this purpose." WHEWELL was not, however, an admirer of excessive height. Amiens Cathedral he considered appeared short in consequence of its height, while Beauvais was absolutely shapeless, and, moreover, the outline of the exterior is obliterated by the number of buttresses. Yet Amiens continued to be one of his favourite buildings. When mentioning a visit to it in 1847, he said:—"It is two or three-and-twenty years since I first saw that building, and it then appeared to me one of the most magnificent works which is to be seen in the world, and so it appears to me still."

There is a vast difference between contemplating architecture with rapture and living amidst building operations. One cannot but pity WHEWELL when we read his account of the alterations at Trinity Lodge. "We had," he wrote, "seven sets of people, whom I used to speak of as our seven plagues, although this was rather an unreasonable way of speaking of them, as they came at our command and did our bidding. These were the masons, bricklayers, carpenters, joiners, glaziers, slaters and bellhangers." He must also have been amused when he received a letter from a contractor which began in the following rather novel way:—"Feelingly alive to this vexatious disappointment, I perfectly dread writing to you. To frame an excuse or falsehood, I cannot, but the truth, which is that the party who undertook the carvings has left me in the lurch; he was an Italian, an exceedingly clever artist; he has pirated our patent and gone to Milan." There is at least one use for foreigners in the building trades, they serve as scapegoats when there are delays. WHEWELL'S most important building work was the hostelry for students, which he erected at his own expense. But after all it cost hardly a fifth of the sum he laid out in connection with the chair of International Law, which amounted to more than 100,000*l.*, and yet in spite of the expenditure nations continue to be at variance.

THE TEMPLE AT NOCERA.

FEW travellers go out of their way to see the temple, which is now a chapel. It certainly does not much merit a sacrifice of convenience, and has little to justify the inflated description of Romanelli. The flooring of this small temple is 12 or 15 feet below the present surface of the soil; in consequence it is not unfrequently flooded, and thus hastened on its progress to ruin. The form is circular and the roof a dome; a conca or large marble basin that offers nothing particular, and that scarcely seems to be ancient, stands in the midst, and occupies one-third of the whole temple; a double row of columns, one row almost touching the other, runs midway between the conca and the walls; of these columns fifteen are of the Corinthian order, without bases. Eight pillars, about 10 feet high, which supported a little dome, were round the elevated edge of the conca, but only four broken ones are now standing. In the workmanship of the columns there is nothing fine. Romanelli says the materials are alabaster, granite and giallo antico; they are thickly crusted with green mould, but, as far as can be ascertained by a little scratching with penknives, they appear to be of no such valuable stuff. This temple suffered a change common to innumerable of its fellows, and altars and figures of saints still occupy the niches of the ancient gods; the accidents, however, to which it was exposed drove the priests to seek a drier spot, and they consequently built a little church that is attached to the temple, but at a level that exempts it from inundation. The temple, the ancient hallowed abode of purity, is now a foul cemetery. Two movable stone flags give access to the vaults underneath; one of these is inscribed *pro mulieribus*, the other *pro sacerdotibus*.

MICHEL ANGELO'S LIBRARY.

IN our notices on the volume on "La Fin de la Renaissance," by M. Eugène Müntz, being the third volume of the Italian Section published by the Librairie Hachette et Cie., we referred to the Laurentian Library in Florence. By the courtesy of the publishers we are able to publish three views of the interior. The building was one of Michel Angelo's earliest architectural works. It owed its origin to Pope Clement VII. He was one of the Medici, and was desirous to have a sacristy and library erected in connection with San Lorenzo as a memorial of his elevation. The commission was given to Michel Angelo. In the sacristy he became an imitator of Brunelleschi, but introducing, as Vasari informs us, details which were not sanctioned by the authority of Vitruvius or by the practice of older architects. In spite of all his admiration for his master, Vasari is compelled to acknowledge that the precedent was not an advantage for art, since it caused other men to employ *grotesque* instead of ornamentation of a proper sort. He has only words of praise for the library. According to Vasari, "the admirable distribution of the windows, the construction of the ceiling and the fine entrance of the vestibule can never be sufficiently extolled. Boldness and grace are equally conspicuous in the work as a whole and in every part; in the cornices, corbels, niches for statues, the commodious staircase and its fanciful divisions—in all the building, at a word, which is so unlike the common fashion of treatment that every one stands amazed at the sight thereof." Visitors to the library do not agree with Vasari in admiring the staircase, for the novelty is obtained by some sacrifice of convenience. But the library was probably better adapted for sixteenth-century readers than can now be realised. The illustrations are truthful, and suggest the care taken with the thousands of examples of all the arts which embellish the volumes by M. Eugène Müntz, and which uphold the credit of the renowned house of Hachette & Co.

very active part in collecting the remains of classical antiquity, so his wealth and extensive commercial intercourse enabled him to gratify his taste to the fullest extent. He enjoined his friends and correspondents, as well as the missionaries who travelled into remote countries, to search for and procure ancient manuscripts in every language and upon every subject. He availed himself of the services of the most learned men, his contemporaries; and the situation of the Eastern empire, then falling into ruins, afforded him an opportunity of obtaining

INTERIOR OF LAURENTIAN LIBRARY, FLORENCE.

many valuable works in Hebrew, Greek, Chaldaic, Arabic and other languages. After the death of Cosmo, his son pursued the same object with steady perseverance, and added considerably to the treasures which had been accumulated by his father. But although the ancestors of Lorenzo de' Medici had laid the foundation of the Laurentian Library, the honour of raising the superstructure belongs to Lorenzo himself, whose assiduity and liberality in enlarging his collection of books, manuscripts and antiquities, were unbounded. To this object his time and his fortune, exceeding that of princes, were equally devoted. Shortly after the death of Lorenzo, however, this matchless collection was dispersed by the Florentines themselves. In the disturbances which attended the expulsion of Pietro, and the approach of the French under Charles VIII. (1494), miserable plunderers openly carried off, or secretly purloined, whatever they could lay their hands on that was rare, curious, or valuable. Part of the library, however, was preserved by the interposition of the magistrates, but only to encounter new perils. The Florentine treasury becoming exhausted, the rulers of the day (amongst other expedients) sold the books to the Dominicans of St. Mark. At this point the history of the Laurenziana becomes linked with the fortunes of the still older library of that monastic community, a collection of which Cosmo may be said to have been the founder, conjointly with Niccolo Niccoli. The 800 volumes (or at least the survivors of them) which Niccoli had bequeathed to his fellow-citizens, and which Cosmo had redeemed from a lien that had well nigh annulled the legacy, and had committed to the custody of the Dominicans, were now united with what remained of the domestic library of Cosmo himself, and of the more splendid acquisitions of Lorenzo. But within two years the misdirected zeal of the impulsive Savonarola—for a while virtual King of Florence—scattered with lavish hand some of the choicest books as presents, and dragged others with con-

BOOK SHELVES IN LIBRARY.

The collection is not without its history. It was commenced, says Mr. Edwards, by Cosmo de' Medici, the father of a line of princes whose name and age, as Roscoe has said, are almost synonymous with the restoration of learning. "His credit," says Gibbon, "was ennobled into fame; his riches were dedicated to the service of mankind. He corresponded at once with Cairo and London, and a cargo of Indian spices and Greek books were often imported by the same vessel." As the natural disposition of this princely merchant led him to take a

tumely to a vast bonfire in the public square. In this wild *auto-da-fé* Boccaccios, Petrarchs and Pulcirs, in all the pomp of their rich illuminations and sumptuous bindings, mingled their ashes. With this result, amongst others—that the frenzied hatred of Dominican monks in the fifteenth century connects itself with the scarcely less frenzied love of English peers in the nineteenth, as cause with effect. Had no Savonarola burnt "Decamerons" in the Florence piazza in 1497, assuredly no Duke of Marlborough would have given 2,260*l.* for a "Decameron" in 1812. After Savonarola's death, the Dominicans, falling into embarrassment in their turn, sold their library (1508) to Pope Leo X, who caused it to be removed to Rome. It was reconveyed to Florence by his successor Clement VII., who, by a bull dated December 15, 1532, made provision for its future security. In 1571 the Grand Duke Cosmo I. made the library public. This library, the noblest monument which the Medicis have left of the glory of their line, contains 6,952 MSS., of which a very large proportion—despite so many losses and very strange vicissitudes—combine rarity and value. They have been described in a catalogue of thirteen folio volumes, compiled by the learned Bandini, formerly librarian, at the suggestion of the Emperor Francis I., who presented him with a sum of money towards the expenses, and made him promises of further assistance, which, however, were rendered unavailing by the death of that sovereign.

The most celebrated manuscripts in the Laurentian Library are the Virgil of the fourth or fifth century, the long missing leaves of which Mai had the good fortune to discover in the

THE LATE REGINALD STUART POOLE.

THE late Keeper of Coins at the British Museum, Mr. Reginald Stuart Poole, died at his house in Kensington on Friday morning, at the age of not quite sixty-three. Since his retirement from the Museum two years ago, after completing forty years of public service, his health had given way, and neither medical science nor change of scene and climate was able to arrest the gradual but premature decay of his energies. Finally a painful affection of the heart, endured with great patience, supervened upon nervous prostration, and the end came. Among the many distinguished scholars of the British Museum none was more popular in a wide circle or more beloved than Mr. Poole. He possessed one of the rarest qualities among men, a remarkable power of sympathy, together with a pure enthusiasm for learning, which made his influence a potent source of inspiration to his students. Few men have done so much by lectures, and still more by personal instruction and conversation, to encourage the study of Egyptology and antiquities among the general public. No head of a department has better succeeded in inspiring his subordinates with a high standard of learned work.

That he should have been able to exert so useful and encouraging an influence in so many departments of learning is the more remarkable when it is remembered that he was, to a great extent, a self-taught man. Born in London on February 27, 1832, the son of the Rev. E. R. Poole, M.A., of Trinity Hall, Cambridge, and of Sophia Lane, a grand-niece of Gainsborough, he was brought up chiefly by his uncle, Edward Lane, the

LAURENTIAN LIBRARY STAIRCASE.

Vatican; the famous "Pandects" of the seventh century, in two volumes, brought to Florence in 1406; a Tacitus, translated in the ninth century from one dated in the year 395; the "Decameron," supposed to have been written in 1384 by Amaretto Mannelli; the "Epistolæ Familiares" of Cicero, copied by Petrarch; a Tasso, with copious notes, in the hand of Politian; and many Dante MSS. of the highest interest, although but copies (Dante's autographs have perished), amongst them the celebrated letter discovered by Melus, and published first by Dionisi and afterwards by Foscolo.

Of printed volumes the Laurentian Library possesses comparatively few, having always been pre-eminently, and until recent date exclusively, a library of MSS. The famous collection of first editions of Greek and Latin classics, formed by Count Angelo d'Elci, formed an exception to the rule, and various other volumes have been presented by the authors.

The English Congregational Chapel Building Society held its forty-first annual meeting at Lewisham on Wednesday. The report showed that since the formation of the Society 830 cases of church extension had been aided, and that the grants and loans (free of interest) had amounted to 160,925*l.*, of which 152,714*l.* had been paid. The total value of buildings and sites thus secured for the denomination was estimated at 1,500,000*l.* The total receipts last year from all sources were 4,778*l.*

Orientalist. In 1842 Mrs Poole and her two sons accompanied Mr. Lane to Egypt, where he was engaged for seven years in accumulating materials for his great Arabic Lexicon. With the exception of a Nile voyage in the company of Sir James Outram, Reginald Stuart Poole spent those seven years in Cairo, where his education was superintended by his uncle and by a scholarly friend, the Rev. G. S. Cautley. His interest and enthusiasm were already engaged irrevocably in the study of Egyptology. So completely did he abandon himself to the study that in 1849, before he was seventeen, he was able to contribute a series of articles on Egyptian chronology to the *Literary Gazette*, which, after his return to England, were republished in book form in 1851 under the title of "*Horæ Egyptiacæ*." Though he saw reason in later years to abandon many of the conclusions there set forth, the fact that at so early an age he should have ventured to handle so thorny a problem speaks volumes for his industry and learning. The book was published under the auspices of Algernon, fourth Duke of Northumberland, the patron of Lane's Lexicon, and the same influence procured Mr. Poole's admission, in 1852, to the department of antiquities in the British Museum before he had attained his twentieth birthday. His reputation was already such that he received his nomination from all the three principal trustees, the Speaker, the Archbishop and the Lord Chancellor. He began very early to lecture, at Brighton and elsewhere, on his favourite topics of Egyptology and numismatics, and in May, 1864, he made his first appearance in a Friday evening lecture at the

Royal Institution, taking as his theme a subject he was never tired of emphasising—the importance of Greek coins as illustrating Greek art. On this subject, above all others, he was a pioneer, and the Munich specialist, Professor Furtwängler, has justly signalled the priority of Mr. Poole's discoveries in relation to the art of Magna Græcia. In a similar manner he brought the evidence of the coins of Camarina to bear upon the interpretation of the fourth and fifth Olympian odes of Pindar.

In 1866 Mr. Poole was appointed Assistant Keeper of Coins, and in 1870 he succeeded Mr. Vaux as Keeper. Thenceforward he devoted himself with exceptional zeal to the primary duty of publishing catalogues of the collections entrusted to his charge. For forty years no catalogue had been published. During his twenty-two years' tenure of the headship of the department he personally superintended and saw through the press sixteen volumes of the "Catalogue of Greek Coins," one of Roman, one of Anglo-Saxon and seventeen of the Oriental catalogues (Arabic, Persian, Indian and Chinese), a total of thirty-five volumes, comprising minute descriptions of many thousands of rare coins, with scholarly introductions, elaborate indexes and a profusion of illustrations. The majority of these catalogues were, of course, compiled by members of his able staff, Dr. Head, Professor Percy Gardner, Mr. Keary, Mr. Grueber and Mr. Wroth, together with assistance from outside specialists such as the late Dr. Terrien de Lacouperie and Mr. Stanley Lane-Poole: but the Keeper himself was personally responsible for the first catalogue published under his régime, that of the "Greek Coins of Italy" (1873), for part of "Sicily" (1876), and he wrote the entire volumes on the coins of "The Ptolemaic Kings of Egypt" (1883), "Alexandria" (1892) and the "Shahs of Persia" (1887). Mr. Poole's conception of the responsibility of the Keeper was, however, excessively rigorous, and, as head of his department, he felt it his duty personally to compare the original coin with the corresponding description of it in the proof-sheets of every one of the thirty-five volumes published under his editorship. These services to science were recognised by the French Institut, which elected him a corresponding member in 1876; Cambridge gave him the honorary degree of LL.D., and he was honorary member of various learned societies.

The remarkable energy devoted to the medal-room did not, however, stifle the old love of ancient Egypt, which was refreshed by an archaeological mission to Cyprus and Alexandria in 1869-70. From time to time he wrote and lectured on Egyptology, and in 1882 he reprinted under the title of "Cities of Egypt" a brilliant series of papers contributed to the *Contemporary Review*. The book was appropriately dedicated to his mother, who had written "The Englishwoman in Egypt" nearly forty years before, and who spent her last years in her son's well-known house in the Museum quadrangle in an atmosphere of filial devotion. When Miss Amelia B. Edwards conceived the formation of the "Egypt Exploration Fund" she found a zealous colleague in Mr. Poole, who took a leading part in all the business of the Society, devoted his utmost energies to its success, and remained its honorary secretary to his death. When in 1885 he succeeded his old friend and colleague, Sir Charles Newton, in the Yates Professorship of Archæology at University College, he converted what had been a chair of purely Greek archæology into a means of general instruction in all the chief branches of antiquities, Oriental, Classical and Mediæval.

Mr. Poole's contributions to literature, besides the books already referred to, were few. He was not a ready writer, and preferred the lecture to the essay. Occasionally he contributed to the *Academy* or to the monthly magazines, and he wrote the articles "Egypt," "Hieroglyphics" and "Numismatics" for the "Encyclopædia Britannica." He also wrote an elaborate catalogue of the Swiss coins in the South Kensington Museum.

TESSERÆ.

Mortar.

IT was found by Berthier after an analysis that Roman cement is composed of carbonate lime 657, carbonate magnesia 005, carbonate iron 060, carbonate manganese 019, clay silica 180, clay alumina 066, water 013. Berthier considered that with one part of common plastic clay, and two and a half of chalk by weight, a very good hydraulic lime could be made, which would set as speedily as the English one; but it is not probable, he allows, that we can obtain by mixtures hydraulic lime which will acquire as great hardness and solidity as the natural mortar, because these qualities depend not only on the composition but also on the state of compactness. The greater density the material possesses, and if it slake without changing its volume, the greater facility will its particles have in becoming aggregated, and the less shrinking will there be during its consolidation. Berthier drew the following conclusions from a numerous set of ex-

periments. A limestone which contains 6 per cent. of clay affords a lime already perceptibly hydraulic. When the lime amounts to from 15 to 20 per cent. it is very hydraulic, and when from 25 to 30, it sets almost instantly, and may therefore be considered as Roman cement. He conceives that the iron and manganese have no effect whatever in occasioning the hardening. In a mortar which owes its solidity to the adhesion of the lime to the alloys, or substances with which it is mixed, there is evidently an advantage in multiplying as much as possible the surfaces of contact. Thus alloys with large grains do not afford mortar so solid as the pulverulent ones, because there are spaces filled with pure lime which do not present the same resistance to fracture as the other parts. On the contrary, alloys in powder, though they present the greatest surface, yet require a very large proportion of lime. To obtain then, with the smallest possible quantity of lime, mortars possessing the greatest solidity, alloys must be used containing particles of different sizes, avoiding always the mixture of argillaceous substances which form a paste with water, but have no coherence. These opinions have been put to the test of experiment on a large scale, the sand usually employed in Paris affording a better mortar when merely washed than when the fine particles are removed by a sieve.

The Founder of St. Bartholomew's.

The first Joculator Regis of whom we have any account is Rahere, who was not only a royal buffoon, but the founder of St. Bartholomew's Hospital and Priory. Dugdale gives an excellent account of the circumstances that led to this merry gentleman's conversion, and induced him after playing the fool for many years to please the court, to play it once more for the benefit of religion and humanity, and finally to become prior of the house he had himself founded. Rahere having spent his youth at court or in the houses of the nobility, to whom his wit and sprightliness rendered him peculiarly attractive, began to repent him of the follies and vanities of the course he had hitherto pursued, and to expiate his crimes, resolved to take a journey to Rome. He did so and fancied all was going on well, when unfortunately he fell sick, and fearing lest he should die in his Holiness's domain, vowed a vow to build a hospital for the poor if he might but recover, and once again reach England. Rahere got better and made good haste to get home. Upon his arrival in England the first thing he did was to consult with his friends how he should commence so important an undertaking, and from them he learned that the site belonged to no less a person than King Henry I. Nothing dismayed, Rahere petitioned his royal master for a grant of the site, which request, backed as it was by the interest of the Bishop of London, was not denied to an old favourite, and he obtained a free grant of the ground and the king's license to build a hospital, church and priory upon it. Rahere's next care was how to clear the ground and procure the proper materials for his buildings at the least trouble and expense, and here tradition relates that he had recourse to his old trade, and effected that by a stratagem which it would have drained his purse dry to have attempted in the usual mode. He feigned himself to be a merry idiot, and collecting a vast rabble about him by his antics and buffoonery, and setting them the example which they as readily followed, he cleared away the rubbish and brought in its room stones and all other the proper materials for his purpose. Having accomplished his design he discovered who he was, set about building the hospital and afterwards the church and priory, all which he finished in 1123 and dedicated to St. Bartholomew. In his priory he placed certain canons regular of the order of St. Augustin and constituted himself the first prior, and presided over his own foundation for two-and-twenty years. In 1133, Henry granted him the privilege of a fair to be kept yearly for three days, the eve, the day and the morrow of St. Bartholomew. The original intention of this fair was for the sale of English cloths, all the clothiers of England and drapers of London having booths and standings in the churchyard, the strangers being licensed for the three days, "the free men so long as they would, which was six or seven days," and this was the origin of the far-famed Bartholomew fair. After continuing superior of his own house till a good old age rendered him fit to be gathered to his fathers, he died in his priory and was buried in the church he had himself erected, where a splendid monument was erected to his memory with the following inscription:—"Hic jacet Raherus primus Canonicus, et primus Prior istius Ecclesie."

The Curfew.

Although there is no evidence to show that the *Couvre-feu* law originated with the Norman Conqueror, yet it appears certain that in 1068 he ordained that all people should put out their fires and lights at the eight o'clock bell and go to bed. But that it was not intended as a badge of infamy is evident from the fact that the law was of equal obligation upon the foreign nobles of the court as upon the native-born Saxon serfs. And yet we find the name of Curfew law employed as a by-

word denoting the most odious tyranny, and historians, poets and lawyers speaking of it as the acme of despotism levelled alone at the vanquished English. However well-intentioned the *Couvre-feu* law may have been, it appears to have met with much opposition, as in 1103 we find Henry I. repealing the enactment of his father. Blackstone says that though it is mentioned a century afterwards, it is rather spoken of as a time of night than as a still subsisting custom. Although the *Couvre-feu* law was abrogated by Henry I. yet the custom of ringing the bell at eight o'clock long continued. In the second mayoralty of Sir Henry Colet, Knt., 1495, this solemn charge was given to the Quest of Wardmote in every ward:—"Also yf there be anye paryshe clerk that ryngeth curfew after the curfew be ronge at Bowe Chyrche or Saint Brydes Chyrche, or Saint Gyles without Cripelget, all suche to be presented." At Ripon, in Yorkshire, a man sounded a horn at the market cross and at the mayor's door at nine o'clock every evening, a custom probably connected with ringing the curfew, which was not always done at eight o'clock. The sexton in the play of "The Merry Devil of Edmonton" (1631) says:—"Well, 'tis nine a'clocke, 'tis time to ring curfew." It is probable in the Middle Ages some superstitious regard was paid to the ringing of the *Couvre-feu*, for we find that land was occasionally left to pay for the ringing of the *Couvre-feu* bell. This feeling appears not to have been altogether extinct even so late as the close of the sixteenth century.

Decay of Buildings.

Those who have for any considerable course of years been in the habit of revisiting any particular ruin can scarcely fail to have observed how sensibly and how surely the course of decay, disintegration and downfall has progressed, even where there has been no deliberate mutilation. In many of the best preserved ruins we find the surfaces of the mouldings and carving covered with an ever-fresh pulverulence. If you visit a building in this exposed condition after a hard winter you are sure to find fresh spots where the details have fallen off through the recent frost, and in every ruin there occur from time to time slips and downfalls of greater or less importance, showing that, long as they have resisted the assaults of time and weather, there are limits to their duration, and that those limits are by no means distant. How many of our ruined buildings have lost large portions within the memory of man. Indeed such downfalls, if their statistics could be collected, would be found to reach an alarming number and amount, while the silent and yet more fatal progress of decay is every day and every hour eating into the most beautiful and most precious architectural details. And how could it be otherwise, when walls constructed of small stone and rubble-work are exposed, with no protection but ivy and wall-plants, to the constant action of the most destructive of climates, when every shower penetrates the crumbling mass and every frost has its full swing in its disintegration, and even the more solid stone, from being kept in a constant state of saturation with water, has every cause of destruction in full and continued operation upon it, and all this for centuries together? Nor have these been the sole agents of destruction. Many—indeed the great majority—of our noblest abbey churches, and even some cathedrals, have been taken down for the value of their materials, and those which were left as ruins were for the most part spared more because there was no market for their material than for any care for their preservation, and it naturally follows that they would become the quarries which would supply all the petty buildings around them. Perhaps the most remarkable case of this is at Reading, where the walls of the abbey have been stripped of their ashlar, both without and within, and the rubble core only left. This has been continued in many instances up to our own day, and even now it is occasionally found in a certain degree to hold good, as at Easby Abbey, in Yorkshire, where the lower part of the buttresses appear to have been comparatively recently pulled down, as being the parts most easily got at, while the upper stages, being out of reach, are left unsupported and dragging over the walls which they were built to stay. For the most part, however, it is neglect and the want of timely care which we have now most to complain of. The proprietors of these melancholy yet glorious remains, though valuing and caring for them as picturesque ruins, frequently seem to forget their value as works of art and to prefer risking their falling to pieces bit by bit to the trifling interference with their picturesque effect which would be incurred by a little timely reparation.

Ethiopian Remains.

Edifices of Egyptian construction or their remains are found along the Nile as far up as Jebel el Birkel, their ages being generally from 1700 to 1400 B.C. The Ethiopian structures, intermingled with or covering them, are of much more recent date (where date is assignable); and the best of them, erected by the Ethiopian kings who ruled Egypt from 719 to 675 B.C. appear to owe their architectural merits to Egyptian skill. Higher up the river the palaces or temples of Beit Naga, Jebel

Calefaat, &c., appear to be of still more recent origin—exhibiting corruptions of the Græco-Egyptian style. The pyramids of Ethiopia are quite modern in comparison with those of Egypt, as their form and mode of construction at once evince. The sculptures with which they as well as the temples are adorned are always inferior to those of Egypt and in general execrably bad. Yet in their style, which differs from that of Egyptian sculpture, they bear to one another that degree of resemblance which characterises one school of art; so that it cannot be admitted that the art of sculpture, as preserved on some of the monuments of Ethiopia, descended the Nile, and reaching its perfection in Egypt, returned after some thousands of years to reassume its old character in Meroe. The hieroglyphics of the Ethiopian monuments are still worse than their sculpture: they are ill cut, ill grouped, and sometimes, through ignorance, inverted or otherwise misplaced. A mistake of this kind may be observed in the signet of Osertasen I., of Egypt, borrowed by an Ethiopian king in an inscription at Jebel Calefaat. Of the origin and rise of hieroglyphic writing in Egypt, no traces can be found, the oldest discovered monuments exhibiting the art already in perfection. The pyramids of Meroe or Assur are considered by Ruppell to be more recent than those of Jebel el Birkel, and were probably erected between 400 B.C. and 400 A.D.

Appreciation of Architecture.

The faculty of appreciation of architectural art has not yet been fully arrived at. It is a faculty which must be cultivated, and it is far more difficult in architecture than it is in painting and sculpture, because, as respects the direct imitation of the works of nature, the three arts of architecture, sculpture and painting have very different powers. Architecture is the least imitative, sculpture is more so, but painting the most imitative of all; and the more imitative an art is, the more easy and the more general will be the appreciation of it, inasmuch as less cultivation of mind is needful for a recognition of the excellences contained in fine transcripts of nature than of the excellences contained in works founded upon conventional forms. Architecture being composed of forms which, though educed from nature, have been adapted to the necessities of building, it is evident that some degree of special education is needful for even a moderate appreciation of its beauties. We have constant evidence of the difficulties of appreciation even among the practitioners of architecture, and largely also amongst amateurs; and thus, for instance, the subject of styles has met with very rough treatment, and even a new style has been proclaimed as the pressing want of the day, which is as much as saying that a new language is necessary to enable modern Europeans to produce noble works of literature. "Style" seems to have been a great curse with many, yet every genuine variety of style demands admiration, inasmuch as no work possesses the quality of style until it has arrived at the condition of beauty. There may be better styles than others, and styles that are more suited for one purpose than another, also styles of greater purity and styles of greater exaltation than others. These, then, all these will be received by the genuine lover of art with feelings of appreciation; and here it must be admitted that the faculty of appreciation is not always as strong in the practical artist as in the amateur or the critic, and perhaps this arises from the wider range taken over the domain of art by the two latter than by the artist, who is sometimes absorbed in his own peculiar walk, and has neither the leisure nor the inclination to study with equal favour the numerous branches into which art is divided. Appreciation is itself an art, and it is honest, discriminating, generous, full of love, full of faith, seeking for excellences rather than defects. Many instances of the want of it have, however, occurred, such as when a really good building has been put into the hands of an architect to alter, he has disregarded the excellences of the older building, and has engrafted upon it his own mode and method with an apparent carelessness about the style and beauty of the original.

The First Antiquarian Society in England.

We first read of an antiquarian society being founded by Archbishop Parker in the year 1570. About twenty of the members were accustomed to assemble from time to time in the house of Sir Robert Cotton. In 1589 the society petitioned Queen Elizabeth for a building and a charter, but with what success we know not. The reputation of the society, however, gradually increased, until it excited the fears of James I., who, alarmed lest it should discuss public transactions, dissolved it. At the commencement of the eighteenth century it again revived, and grew into such importance that in 1751 the members obtained a charter of incorporation, the power to constitute statutes and to act under a common seal. The original object of their inquiries appears to have been British antiquities and history, although the enlarged operations of the society now embrace every subject of ancient and Mediæval relics and traditions. From the cultivation and extension of this antiquarian taste has sprung our modern institutions of similar tendencies.

NOTES AND COMMENTS.

THE sub-committee of the Glasgow Corporation entrusted with the charge of the galleries and museums have acted wisely in giving 525*l.* for the *Vanity Fair* of Mr. J. E. CHRISTIE. For the majority of frequenters of galleries modern works alone are attractive; the "old masters" are beyond their comprehension. It is easy to pretend that one possesses the faculty for appreciating the charms of dull landscapes, gaunt figures, mythologies, but it is not right to encourage that sort of hypocrisy. All artists have to think about the wants of their contemporaries, and those of Italians and Dutchmen differ from the wants of our time. At present there are far too many works in the Glasgow galleries which cannot be understood by the people, and it is to be hoped that in the new galleries a more satisfactory proportion of modern works will be visible. Mr. CHRISTIE'S *Vanity Fair* is of the kind that is suitable. He always succeeds in compelling attention to be given to his works. He has the gift of imagination, although no realist works harder to attain truth, and his colour is generally satisfactory. Why Mr. CHRISTIE has not attained a more prominent position probably could be explained by the picture dealers. But the citizens of Glasgow may be assured the money laid out on the *Vanity Fair* was well invested, for the picture will give far more pleasure than any of the ancient masterpieces which would be obtainable for the same money.

THE Classic temple at Nîmes known as the Maison Carrée is one of the most interesting of Roman buildings, and France may well be proud of such a possession. It will soon become still more precious in the eyes of architects. Professor GOODYEAR, who of late has been exercising a very keen American intellect in an independent study of ancient buildings, asserts that, as in the Parthenon, extremely subtle curves are to be found in the Maison Carrée in parts which are generally supposed to be planes. He maintains that all curves in architectural surfaces, whether concave or convex to the point of vision, produce an effect of dimension conditioned by the laws of curvilinear perspective, and that the curves of the Maison Carrée have been hitherto overlooked for this reason. Professor GOODYEAR has taken the precaution to have the measurements proving the curves to exist in the masonry constructed attested by the official architect of the city of Nîmes, with whose co-operation and assistance the measurements were made. The curves differ from those of the Parthenon, being curves in plan (not in elevation), and are convex to the point of vision. The measurements also indicate a perspective scheme in the intercolumnar spacings. Hitherto it was not supposed that the Roman mind cared for subtleties of the kind, and it is believed the Maison Carrée is the first building of the style in which they have been discovered.

WE have seen some samples of the plates from the important work "London Churches of the Seventeenth and Eighteenth Centuries," which Mr. B. T. BATSFORD is preparing for publication. As illustrations of buildings they will sustain comparison with those in the volumes on English Renaissance issued by the same publisher, and higher praise could hardly be given. It is a trait in our national character to undervalue many things which we possess, and hence fine buildings, which, if found abroad, would receive unstinted admiration, have been neglected. The new work will crown the reaction which began some years ago, for it will demonstrate that many of our London churches are not only effective as buildings, but that their details will sustain a microscopic scrutiny. If, for instance, the organ case of St. Lawrence Jewry were found in Vienna, every inch of the carving would be copied by artists from all parts of the world. WREN was anxious to have some means of obtaining copies of the work in the Paris churches, but we cannot recall one which shows finer Renaissance detail than is shown in the plate of the south choir aisle of St. Paul's. It is proposed to illustrate at least thirty-six of the churches by the aid of photography, for in no other way could justice be done to them; but ground-plans and drawings of parts will also be furnished. The whole work will be produced

under the editorship of Mr. G. H. BIRCH, who may be said to have devoted his life to the study of the architecture of London, and he is therefore pre-eminently qualified for the task. The price to subscribers will be three guineas, which is at the rate of a shilling a plate, and for that price only smaller, inferior, and less useful photographs are at present to be obtained. Considering its beauty and technical value, the new work will be a marvel of cheapness.

It is a pity that Englishmen are holding aloof from all archæological enterprises in Greece, with the exception of a little pottering which may help to entertain a few ladies and officials. Allow the Germans any sort of introduction, and they turn it to account most effectively. The latest example is Professor DURM, who was summoned to give advice about the condition of the Parthenon. Having accomplished the first part of his work he immediately utilised his opportunities to do something else which has been long neglected. He proposes to arrest the further decay of the Lion of Chaeroneia, of which the existence is unknown to most English travellers. Professor DURM has no wish to restore the figure, which at one time was so expressive of action, but he believes fragments could be obtained which would make the body less imperfect, while many pieces of the pedestal could also be gathered and put together in the same way, and again made to sustain the lion. If he succeeds he will have gained another triumph for German archæology, for although many years have elapsed since the body of the lion was exhumed, a really earnest effort to explore the ground for fragments was never accomplished.

AT a time when the question of simple or compound Portland cement is under discussion, as well as the relative merits of English and foreign, the appearance of Mr. REDGRAVE'S "Calcareous Cements" (CHARLES GRIFFIN & Co., Limited) is most opportune. The subject is considered from many points of view, and the information has the precision which is desired by the practical man. The processes of manufacture, English and foreign, are described, and architects and engineers are informed about the tests which should be employed and the specifications to be adopted. The chapter on the employment of slags for cement-making will probably first receive attention, and we may say that Mr. REDGRAVE is in favour of combinations which are undervalued because they have received the evil name "adulterated." The success of mixed cement does not uphold the accuracy of the ordinary theory of cement, but it does not follow that the tests are incorrect. Mr. REDGRAVE recognises the difficulties, and on that as on other accounts, his pages are worth study.

THE edition of the London Building Act by Messrs. W. RUSSELL GRIFFITHS, LL.B., and F. W. PEMBER, M.A., published by W. CLOWES & SON, Limited, forms a thicker volume than the various editions which appeared before it. The difference is owing in the first place to the number and length of the notes, which have been prepared with much care and refer to a great variety of cases. The treatment of the other statutes, of which parts at least are still in force, is no less systematic. The City of London Sewers Acts are also given, as well as the by-laws and regulations which are in force within the City. The printing is of a kind that will diminish the labour of consultation, and it is an advantage to have ample margins for recording memoranda. The editors do not claim for their volume that it is absolutely exhaustive, but for architects and builders it deserves to be considered as coming as near to that standard as will be ever needed. It is well worth the publishers' price.

LOCKWOOD'S "Price Book for 1895" is not only thoroughly revised and brought up to date, but in some sections has been scrutinised by experts. The new Building Act has been printed as a supplement, in full, with notes and explanations by Mr. DAVID, LL.M. Quality and quantity are, therefore, combined at the cheapest rate for the advantage of Messrs. CROSBY LOCKWOOD & SON'S numerous patrons in the building trade.

REFRESHMENT BARS.

ON Tuesday, December 18 last, this theatre, having been closed for three months and reconstructed in that time, opened its doors to the public.

The first theatre on the present site was erected in the year 1827. It was burned down on February 13, 1856, and reopened on November 30, 1858, under the title of the "New Royal Pavilion Theatre, or the Great Nautical

PAVILION THEATRE—FIRST FLOOR.

Theatre of the Metropolis," having been rebuilt by the late Mrs. DONALD MUNRO in the interim.

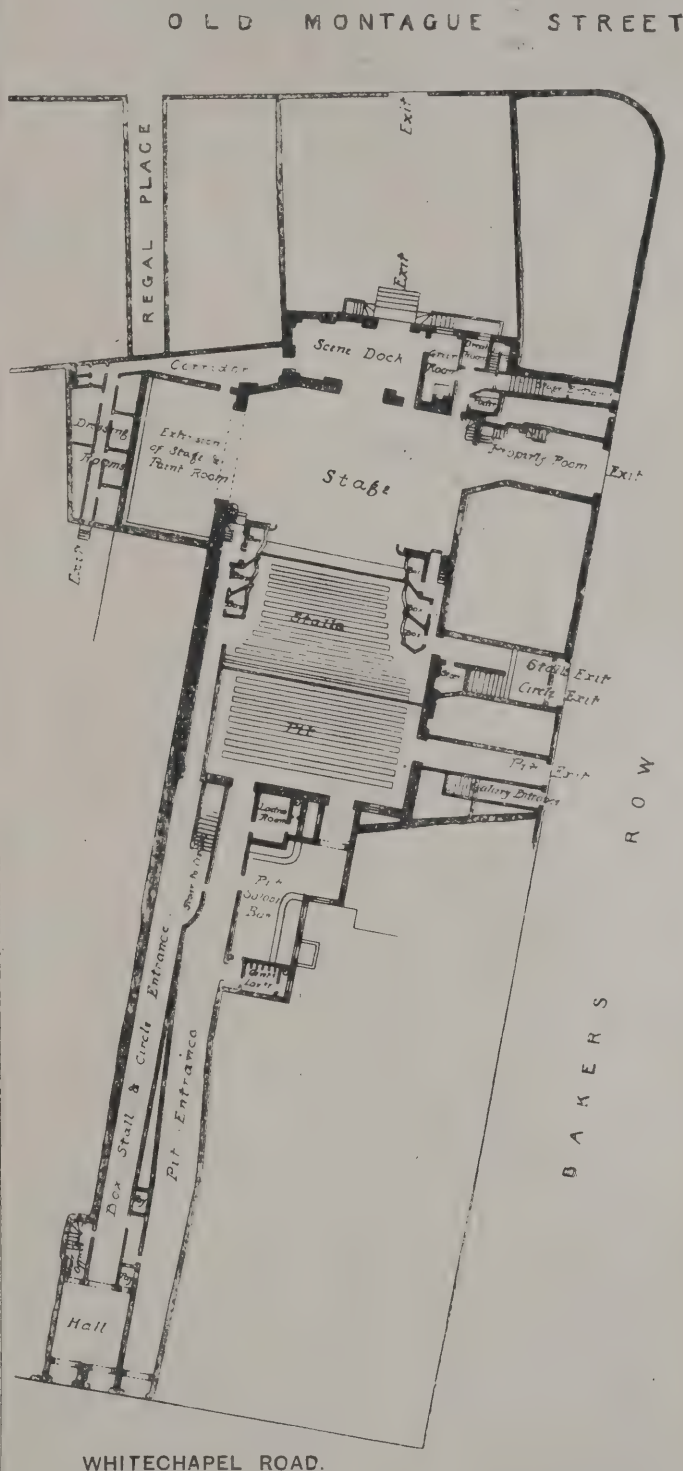

Practically the main walls are the only portion of the theatre of 1858 left standing, and even they have been considerably extended.

The task of altering and adding to the property was commenced in August last, but it was not until September 21, when the theatre was closed, that the very extensive alterations were seriously started. Within one week of this date the work of demolition was almost complete, and it is difficult to realise that in so short a period so much has been accomplished.

The one approach from the main road (always a drawback to this theatre, by reason of the intermixing of pit, boxes and stalls) has been entirely remodelled, and is appropriated to the stalls, boxes and grand circle only, and

for the pit a large area of ground has been acquired and a new approach erected adjoining the principal entrance.

The main entrance in Whitechapel Road has been entirely reconstructed; the design is Renaissance of simple yet bold outline. It is built entirely of terra-cotta, manufactured by Messrs. DOULTON. The three approaches are separated by Doric pilasters and piers surmounted by an entablature of the same order with a balustrade over. From the end piers rise coupled Corinthian pilasters surmounted

PAVILION THEATRE—GROUND FLOOR.

by a semicircular arch 16 feet in diameter. Somewhat recessed on the first floor is the Board-room, above which is a circular opening for illuminated advertisements and notices of the entertainments taking place. The space surrounding this circular opening is occupied by figures of Tragedy and Comedy, with Cupids and drapery above. The whole of these have been modelled by Mr. WILLIAM NEATBY, who has appreciated his subject and carried out the work in a masterly manner.

Those who remember the old refreshment bars (now entirely absorbed by the approaches) will appreciate the improvements in this department. In place of the cramped accommodation, spacious and cheerful saloons have been arranged on the site of adjoining property. Teetotal bars, with fruit and confection rooms for ladies and children, in addition to the ordinary buffets, are provided. The whole of the bar fittings have been specially prepared by Messrs. FARROW & JACKSON.

The auditorium has been considerably altered, the old ceiling removed and a new one erected at a greater height, thereby giving an uninterrupted view from the gallery. This ceiling, a special feature in the building, is designed in the style of the French Renaissance, the centre portion being clouded and richly painted by Messrs. NEPPER-SCHMIDT & HERMANN with allegorical figures and cupids; the boxes, too, have been transformed and enriched with classic columns, &c., the circle and box fronts have also been improved. The level of the pit and stalls has been altered, and the house generally has lost its former dwarfed appearance, and is now lofty, well ventilated and of good proportion.

The whole of the auditorium has been redecorated, re-seated and reupholstered, the latter portion of the work being entrusted to the well-known firm of A. R. DEAN, of Bull Street, Birmingham.

The general scheme of decoration is in modified primary tints, viz. terra-cotta walls of "Muraline," with Axminster carpets to correspond, old gold and electric blue upholstery, and the circles treated in blues, creams and gold.

A handsome plush tableau curtain now replaces the old green cloth, and an act drop of the latest East End improvement, to wit, the "Tower Bridge," has been painted by that popular scenic artist, Mr. J. HARKER, of Lyceum and Haymarket fame.

Probably the most extensive alterations have been made on the stage. Here the old roof has been removed, the building carried 32 feet higher, and a huge mansard formed, having a total span of 64 feet. On the west side the stage has been extended and a painting room provided; beyond this is a suite of cosy dressing-rooms, with every appliance for the comfort and convenience of the artistes. At the back of the stage the dressing-rooms have been entirely reconstructed with fireproof floors and partitions. On the stage level are the hall, green-room and quick change room, whilst in the basement a room for the orchestra is provided, with music store, &c., and emergency exit. Here, too, is the chamber for the electric installation by Messrs. MOODY BROTHERS, of 66 Victoria Street, Westminster, replacing the old limelight apparatus.

A new stage has been laid, with all modern improvements, by the company's stage machinist, Mr. J. WICKS; iron circular staircases replace old wooden ones, and in fact all stage appliances have been completely modernised at great cost, thus enabling the company to place before the public productions hitherto impracticable at this theatre.

Gas is still adhered to, except for the stage, as before mentioned, the auditorium being lighted by incandescent gas-burners, which have been supplied by the Incandescent Gas Company, of Westminster. There is a complete set of hydrants in the building, supplied by MERRYWEATHER & Co., of Greenwich.

The company have endeavoured to bring this theatre thoroughly up to date, feeling that in doing so and giving good value for money, the success of this old-established property will not only be maintained thereby but largely increased.

The company desire to acknowledge and thank the contractors, Messrs. COLLS & SONS, of 5 Coleman Street, E.C., for the very excellent and expeditious manner in which they have carried out the whole of the exceedingly heavy and responsible structural alterations and decorative work.

To Mr. T. J. COLLINS, of Messrs. COLLS & SONS, who had the management of the works, and to Mr. JARVIS, their foreman, great praise is due for their indefatigable efforts and organisation, and also to Mr. G. McLEAN FORD, A.R.I.B.A., who acted as clerk of the works throughout.

The whole of the structural and decorative work has been carried out from the designs and drawings and under the personal superintendence of Mr. ERNEST RUNTZ

architect (of the firm of Messrs. S. WALKER & RUNTZ), 22 Moorgate Street, London, E.C.

The mosaics are by the Vitreous Mosaic Co. The photographs from which the illustrations are taken are by the WILTONS, Limited, with the exception of the front, which is by Mr. A. BINNIE.

We understand that Mr. ERNEST RÜNTZ is well forward with his designs for the new Theatre Royal at Cambridge, which is about to be built for Mr. W. B. REDFERN, J.P., D.L. of Cambridge. Building operations will commence at the end of April or early in May. We shall publish the views of the Cambridge Theatre in due course.

The whole of the Mansfield Woodhouse stone used in the New Municipal Buildings at Burton-on-Trent, given by Lord Burton, and illustrated in last week's *Architect*, was supplied from the Pleasley Junction Quarries, Mansfield Woodhouse. These quarries have only been open a few years, and the finest quality stone is obtained from them. Mr. William Sills, Mansfield Stone Quarries, Nottinghamshire, is proprietor.

SOCIETY OF ARCHITECTS.

A MEETING of this Society took place on Tuesday, the 15th inst., Mr. Hamilton in the chair. The Rev. J. Cave-Browne, M.A., read the following paper on

The Parish Church of Maidstone: Its Architecture and Archæology.

The Rev. CAVE-BROWNE said:—Before entering on a detailed examination of the church itself, it may be interesting to see what can be gathered from early writers and from recent discoveries as to the existence of any previous building on this site. Without reviving the old controversy as to the original name of Maidstone, whether or not it was the Vagniacæ of Antonine, so called from the vagaries of the river on which it stands, or why it was called by the Saxons "Medwægestan," according to Camden, it is evident that it must once have been a Roman settlement, as most interesting discoveries in the neighbourhood show. From its position, lying in a nearly direct line between Richborough, or Dover, and London, it was most probably an important military station, and as such would have its curia or basilica and its templum. It may then be fairly inferred that here, as in so many other places, St. Paul's to wit and Westminster Abbey, the basilica or temple would be converted into a place of Christian worship, to be replaced in due time by some more strictly ecclesiastical building as Britain became Christianised.

The first actual mention of a church existing in Maidstone is to be found in the Domesday Record, where it is expressly stated in the survey of the manor (*Ibi Ecclesia*). The next reliable source of information, after an interval of 300 years, is in the Lambeth Registers, where it is recorded that in the later years of the thirteenth and the beginning of the fourteenth centuries Archbishops Winchelsey and Reynolds frequently held ordinations here, showing that even then Maidstone was an important ecclesiastical centre, and could boast a church capacious enough for so imposing a function.

Whether any portion of that building still remains is very doubtful. During the recent restoration under Mr. Pearson an interesting discovery of Mediæval tiles was made, lying *in statu quo* about a foot below the present floor level, which were probably of the early part of the fourteenth century. The designs were heraldic, of the current style of that period, *fleurs-de-lis*, lions rampant, chevrons, quatrefoils, &c., but seeming to give no clue to the probable founders of the building. At the same time it was discovered that the piers of the south aisle were built upon bases of a much ruder and more massive character, of oval form, and having a slightly more southward inclination, showing that the present one occupied, with very slight deviation, the site of an earlier church. Then a further discovery was made in the chancel under the choir stalls of a few tiles of much finer workmanship, representing a bishop and a king, each seated, which were pronounced by the Society of Antiquaries to be of a rather later date than the others, and probably designed for mural decoration. These also evidently belonged to the earlier building.

What, then, it may now be asked, is the probable date of the present church? A casual glance at it, with its broad-spaced windows, prolonged mullions, and scant mouldings, would no doubt suggest that it was, what local tradition pronounces it to be, the work of Maidstone's great Archbishop Courtenay, at the close of the fourteenth century, and as such a fine specimen of the Transition between the later Decorated and the Perpendicular, then coming into fashion.

But a closer examination would seem to point to an earlier

date. Take, for instance, the tower, which, as in so many churches in Kent, instead of being at the west end, stands out on the south side. Its bold buttresses, the roughness of the masonry and the two-light windows of the upper storey belong rather to the earlier than to the later years of the fourteenth century. Another feature of the tower is also noteworthy—a projecting turret on the inner angle, like that at Herne Church, anticipating, as it were, what came to be so frequent an arrangement in Kent during the Perpendicular period.

It may be here mentioned, before passing into the interior, that this tower, so massive and broad, from whatever point you look at it, except perhaps the river side, conveys the impression of being disproportionately low, having a stunted or dwarfed appearance. This may be explained by the fact that there originally arose a graceful spire, as is represented on the old municipal seal of the borough, which spire was struck by lightning and destroyed, never to be rebuilt, in the year 1730. Up to that time the spire-topped tower gave that elevation and dignity to the entire building which, unfortunately, it now lacks.

On entering the building, further evidence meets us of its earlier date than the Courtenay era. At the western end of the south aisle is an Early English doorway, which formerly gave access by a newel stair to the belfry in the tower. Then in the north wall near the east end is a similar doorway opening into a broad buttress, where a winding stair led up to the rood-loft. Again, at the eastern end of the south aisle are the remains, though sadly mutilated, of a richly decorated piscina, to which happily a definite date can be assigned, for the Lambeth Register tells us that in the year 1369 a license was granted to Robert de Vineter (or Vyntier, as he is sometimes called) to endow a chantry at the altar of St. Katherine, already existing, with lands on "Gould's estate," from whence this was known as "Vinter's" or Gould's chapel. Also in the clerestory windows are remains of decorated tracery. Are not these confirmatory indications that, despite the local tradition and current opinion which claim for Archbishop Courtenay the credit of having been the real builder (*fundator*) of the present church, what he really did was more likely the utilising the shell (so to say) of the then existing building, and inserting Perpendicular windows and substituting the light and graceful columns for the more substantial ones of the preceding period, and supplying a fitting endowment.

Then, again, the windows themselves, especially those on the north side, would seem to confirm this view. They are all of four lights and of the same width, while the spaces which they occupy between the buttresses vary considerably; several of them are so squeezed in that in some the corbels or returns of the hood-mouldings are buried behind the buttresses, while where they clear the buttress the masonry round gives indication of insertion, while the stonework in the upper portion of the walls differs in character from that of the lower part. Now had they formed a part of the wall as it was originally built, may it not be assumed that, rising with the wall, the windows and the spaces they were designed to fill would have been proportioned and adapted to each other?

Having dealt so far with the structural features of Archbishop Courtenay's work, we would pass on to consider the ecclesiastical and financial character of the changes he introduced. He found St. Mary's, as it then was, a rectory evidently very poorly endowed, and served by a rector and one or more curates, having the small churches of Detling and Loose (two villages about two and a half miles on either side of the town) attached to it as chapels-of-ease, dependent on the mother church for their ministrations. But on the other side of the river, a short distance off, he also found a well-endowed *hospitium*, or hospital, really a rest-house for pilgrims on their way from the west to the shrine of St. Thomas of Canterbury, having its chapel, refectory, dormitories, &c., with its staff of warden and fellows, or *corrodors*, for the purpose of supplying hospitality and ministering to the wayfarers. This had been the work of Archbishop Boniface in the middle of the thirteenth century, dedicated to SS. Peter and Paul, by which he hoped to condone an act of Savoyard cruelty he had perpetrated upon the prior of a small *hospitium* in Southwark which came under his patronage and jurisdiction. A passing word may here be spared for the chapel of this *hospitium*, all that now remains of it. It had been for years neglected, and eventually converted into a store-shed of a contiguous brewery, but was rescued and restored to its sacred use about sixty years ago under the present name of St. Peter's Church. The east end has been preserved. There may still be seen its beautiful deep-played lancet windows, with their graceful Purbeck marble shafts, one of the architectural gems of the town of Maidstone.

Now, in Archbishop Courtenay's time the enthusiasm for pilgrimages had become less eager, and so this hospital had begun to lose much of its original purpose, and was lying comparatively useless and idle, while it encouraged idleness in its members in these days of its decline, consisting chiefly of inferior dependents of preceding primates. Here Courtenay

saw his opportunity; as patron of both hospital and rectory it became easy for him, under the King's sanction, to transfer the revenues and advowsons of the one to the other, and thus to give greater efficiency to the ministrations of the church in the town. So he turned the rectory of St. Mary's into the collegiate church of All Saints, replacing the rector and his curates by a warden and six canons, with a full staff of subordinates, and erected for their accommodation the college close by, with its goodly range of buildings.

We must now pass into the interior of the church. The eye is at once struck with its spaciousness, the lightness and elegance of the pillars; the whole area, now divested of the heavy galleries which, until its recent restoration, blocked up the side aisles, displays a clear expanse, unrivalled by any church in the county. Its symbolical proportions, too, brought out with so much force and feeling by the present Archbishop on the occasion of its opening service after the restoration, demand a passing notice. The nave is just 99 feet long and 93 feet wide; the choir proper is composed of two squares of 60 feet each, making a depth of 120 feet by 60 feet wide; the two side aisles of the choir are of corresponding length with the choir itself, and each 12 feet wide. Here we have in each part and each way, in the nave, the choir and the chancel aisles, multiples of the figure 3. Can this be accidental? asks the Archbishop. Was it not designed to keep constantly before and impressed on the minds of the people the great cardinal doctrine of the Christian faith—that of the Triune God.

The interior arrangements of the church are sufficiently preserved to enable us to consider them in detail. Here were clearly five altars; the east ends of the side aisles of the nave and of the chancel were so appropriated, as well as the high altar. That dedicated to St. Mary, the patron saint of the original church, occupied the end of the north aisle, of which not a vestige remains, though on the angle on the outside corner is still to be seen a small canopied recess in which no doubt the image of the Virgin formerly stood; at the end of the south aisle was the altar of St. Catherine already alluded to, and here are the mutilated remains of a once beautiful piscina, hewn and chiselled away to make room for a staircase up to a gallery; the south aisle of the chancel contained the altar of St. Thomas, but here all trace of piscina and credence have been obliterated by ponderous modern monuments; then in the opposite chancel aisle stood the altar dedicated to the use of the "Corpus Christi Fraternity," who once held an important position in this town, their ancient home in Earl Street, used for many years after its suppression as a grammar school, now converted into a brewery store-shed and workshop.

In this chapel nothing remains but the step on which the altar stood. We have next to speak of the high altar at the east end of the choir itself; all that now survives to tell its tale is a very handsome and noteworthy four-seated sedilia, all on one level. The chancel arch was no doubt once spanned by a conspicuous rood-loft, to which access was apparently obtained through the turret stair in the north wall, and across the north aisle, where probably a smaller rood marked the entrance to the chapel of St. Mary. All indication of the central or side rood-loft has disappeared in the piers of the chancel arch and the north wall.

When we come to speak of the monuments it must be admitted that, taking into account the age and importance of the church, it is not so rich in them as might have been expected. The one which, had it escaped the ruthless hands of General Fairfax's Parliamentary troopers, would have been the glory and pride of the church is that which commemorates the noble-born and noble-minded West of England Primate Courtenay, whose affection for the place was evinced in the renovation and endowment of the church. On the pavement in the centre of the choir lies a massive slab of Bethersden marble, of unusual proportions, which once covered an altar tomb. On it may still be traced outlines of a matrix of a sumptuous brass representing the figure of the good archbishop in full pontificals, under a richly wrought canopy. This, despite the rival claims of Canterbury Cathedral to his burial-place under an unnamed and unadorned tomb, marks the spot where rest the bones of Courtenay, as was proved by a careful examination of the tomb by experts at the close of the last century, thus establishing the fact that the one at Canterbury ascribed to him is but a cenotaph, erected by the monks of the Christ Church Abbey to fabricate a spurious claim for their cathedral to have the honour of being the resting-place of so distinguished a Primate. This goodly slab has known many vicissitudes; once, as has been said, covering a handsome altar tomb, which was pronounced to be an obstruction, it was lowered to within a foot of the pavement, but being still an obstruction, and being moreover degraded to the use of a bench for the Sunday school children to sit upon, it was deemed, if not more dignified, at any rate less open to desecration, to lower it to the pavement, where it now lies.

Only second in interest to that of the second founder of the collegiate church is the altar tomb of its first warden, Thomas

Wotton. In accordance with the wish expressed in his will, he was buried in the chapel of St. Thomas, subsequently known as the "Arundel Chapel" from the fact of this elaborate tomb having been erected by Courtenay's successor in the see of Arundel over their mutual friend Wotton. It is as remarkable for the richness of its architectural details as for its heraldic adornments; perhaps still more for the singular fresco which covers the wall at the back, where, with St. Katherine and St. Thomas standing by, an angel is presenting the soul of Wotton before the Virgin Mary seated on her throne. This wall could not have been contemporary with the tomb itself, but was clearly an afterthought, introduced doubtless to serve as a background to the beautiful sedilia, which present the rare feature of being four in number and all on one level.

A third altar tomb once stood in the choir, but, like that of Courtenay, is now level with the pavement. Tradition has it that this was the burial-place of a member of the Woodville (or Widville) family who then owned the mote—either the grandfather or the father of Elizabeth Woodville, who became queen of Edward IV. The matrix on the stone is now so worn that no conception can be formed of its design, save that it represented two separate figures lying side by side. A rough outline sketch of it was made by the learned antiquary and unwise politician Sir Edward Dering, and was preserved among the (now apparently lost sight of) "Surrenden MSS.," of which, however, a copy was given in the first volume of the "Archæologia Cantiana."

From these monuments of the fourteenth and early fifteenth centuries we pass—with the exception of a singular copper plate on the wall of the chancel pier, which records no less than seven generations of the old Maidstone family of the Beales (and by its side one to the Tufton family, then owners of the mote), from whom the distinguished local antiquary Beale Poste claimed descent—to a group of monuments of a very different character, belonging essentially to the Tudor and Stuart periods, of the Astley and Knatchbull families. These originally stood in the chancel, to the sore obstruction of the sedilia, which had been chiselled away to make room for them, and blocking up the east wall of the church. But on the recent restoration of the church under Mr. Pearson they were moved away and arranged against the west wall, where they are less obtrusive and appear to far greater advantage. The first of this group is a colossal tomb of grey alabaster, rising some 20 feet from the floor, in two stages, commemorating two generations of the Astley family. In the upper one are the figures of John Astley, master of the royal jewels and plate under Elizabeth, with whom indeed he claimed kinship, as his mother's sister married Sir Thomas Boleyn and became the mother of the ill-fated Anne Boleyn, and by his side the figure of his wife. In the lower portion, again, are two figures, those of his son Sir John Astley, who was also a Court favourite, and was master of the revels under James I. and Charles I. By the side of this tomb is one of a very different character and to the memory of a very different man, who, as his cousin, succeeded to the property of Sir John. This was Sir Jacob Astley, whose memorable prayer, "O, Lord, if I forget Thee to-day do not Thou forget me," before going into the battle of Edgehill, has given him a place in English history. His monument consists of what is called a herse—a flat white marble slab, with his shield in the centre.

By the side of the group of Astley monuments is one of Knatchbulls of Merst Hatch, into which family a daughter of Elizabeth's John Astley had married. On this long flat monument appears a long Latin inscription recording the alliances of the sons and daughters of Sir Thomas Knatchbull, who married into some of the leading families of the county, a Curteis of Tenterden, a Toke of Godington, a Chute of Appledore, and others, the whole proclaimed on seven richly emblazoned shields which run along the frieze of the monument.

A vote of thanks was proposed by Mr. H. Lovegrove, A.R.I.B.A., seconded by Mr. Ellis Marsland, and supported by Messrs. H. G. Quartermain and Middleton.

EGYPTIAN CHRONOLOGY.

THE "Horæ Ægyptiacæ" of the late Reginald Stuart Poole is a work that is less known than it deserves. That so abstruse a subject was treated by a youth of seventeen is one of the most remarkable feats in the history of scholarship. Probably Mr. Poole may have had the advantage of manuscripts by his relative, Mr. E. W. Lane, who lived in Cairo. As a sample of the work we give what is practically the concluding chapter. It relates to the first nineteen dynasties, which seems best adapted for reading by those who are not specialists. The preceding parts afford a better notion of the author's learning:—

We have now to consider the most brilliant period of Egyptian history, the rule of the eighteenth and nineteenth dynasties, during which the kingdom rapidly rose in power, until the shepherds were wholly expelled and the nations of Asia and Africa, from the Tigris to Abyssinia, were reduced

to tributary states, under the control of the Pharaohs. A complete examination of Manetho's lists and the monumental history of these dynasties would fill a volume; and, therefore, I must confine myself chiefly to certain remarkable points upon which I conceive new light may be thrown.

The chronology of the eighteenth and nineteenth dynasties presents remarkable difficulties which the numerous monuments of the time do not enable us completely to clear up. These difficulties are chiefly occasioned by the repetitions of certain kings' names and reigns, from some errors in the lengths of kings' reigns, and from the reckoning of some contemporary kings as successive, in Manetho's lists. With respect to the chronology of these dynasties, in addition to the dates which I have before mentioned, all that can be said with certainty appears to me to be that the eighteenth dynasty commenced about B.C. 1570, at the commencement of the great Shepherd War, and that the nineteenth ended somewhat more than 300 years afterwards, about the middle of the thirteenth century B.C. These approximate dates agree with the two dates of the reigns of Amenoph II. and Rameses II., which I have previously pointed out.

Let us now examine more particularly some of the events recorded by Manetho and the monuments. Abstaining from entering upon the subject of the foreign wars of the Egyptians—a subject which would require much larger space than I can here devote to it—I shall only notice one fact relating to these wars, namely, the total silence of the Scriptures as to the expeditions of the Pharaohs. To ascertain the cause of this silence, we have in the first place to consider the nature of that part of the sacred records which relates the history of the Children of Israel during the interval in which the great conquests of the kings of the eighteenth and nineteenth dynasties were achieved. The Book of Judges, which contains the history of this period, narrates the servitudes of the Israelites, their deliverances, and the periods of prosperity following those deliverances. The durations of the servitudes and times of prosperity are given with scarcely any notice of remarkable events which happened during those periods; but the successful efforts of the Israelite leaders to free their country from foreign tyranny, and the circumstances of each deliverance, are much more fully narrated. Hence we can easily see that the Book of Judges, like the historical parts of the Pentateuch, is an account of God's dealings with His people, of the punishments which He inflicted on them for their sins, and the leaders whom He raised up to deliver them when they had repented. We may, therefore, readily believe that Egyptian armies passed through Palestine, and that their passages are not recorded in the Book of Judges, because they neither conquered the Israelites nor made them tributary. That they did not do so I consider almost certain, since I find no names of towns of the Israelites, nor names of the tribes, in the lists of towns and peoples and countries conquered or made tributary by the kings of the eighteenth or nineteenth dynasties, although we do find such names in the similar list of Sheshonk I., the Shishak of the Scriptures. Hence it appears highly probable that the Pharaohs of the eighteenth and nineteenth dynasties never attacked the Israelite possessions during the times of the Judges, and their reason for not doing so must have been that they well knew the calamities which their predecessors had brought upon themselves and upon all Egypt by their cruelties to the Israelites. The same may be said of the kings of the twentieth dynasty.

I have already mentioned that Thutmosis, or Thothmes IV., expelled the shepherds, and I have nothing now to add to what I have before said on this subject, except that the silence of the monuments as to this important event is easily to be explained. For we find that nothing which the Egyptians considered as not creditable to their valour is ever recorded on the monuments, and consequently we cannot expect to find on them an account of a transaction in which an Egyptian army of 480,000 men was unable to reduce a fortified place defended by a force of shepherds of about half their number.

The next remarkable event after the shepherd-exodus was the settlement of a foreign tribe of sun-worshippers in Egypt, and the subjugation of the whole country by them. This event seems to have been noticed by Manetho, for Eusebius, in the second part of his chronicle, mentions that during the reign of Amenophis (Amenoph III.), the seventh king of the eighteenth dynasty, "the Ethiopians, migrating from the river Indus, came and took up their habitation near to Egypt;" and Syncellus, in his "Laterculus," inserts the following sentence between Amenophis and Orus:—"The Ethiopians, coming from the river Indus, took up their habitation near to Egypt." Of course this statement would be of little value if resting solely on the authority of Syncellus; but when we find it also in the chronicle of Eusebius it becomes highly probable that it was originally derived from Manetho or some equally trustworthy authority; and the fact that Egypt and Ethiopia, the latter perhaps first, were some time under the power of foreign chiefs about the time mentioned by Eusebius, proves the genuineness of the statement.

The position of the eastern Ethiopians is easily fixed, from the accounts of Herodotus and others, whence we learn that they chiefly inhabited Gedrosia and Carmania, and it is probable that their territories did not extend further eastward than the river Indus. Herodotus, in his enumeration of the army of Xerxes, mentions them as a long-haired people, to distinguish them from the woolly-haired western Ethiopians who inhabited the countries watered by the Upper Nile. The Cuthites, or inhabitants of Cuthah, placed by the king of Assyria in the cities of the ten tribes, may be the same people (*vide* 2 Kings xvii. 24, 30).

The earliest indication of the presence of the sun-worshippers in Egypt is in the time of Amenoph III., in an inscription on a scarabæus, with the date of the eleventh year of his reign, in which their god, Atenra, or the solar disc, is distinctly mentioned (see Rosellini's "Monumenti Storici," plates, No. xlv. 2). This furnishes us with a strong reason for adopting Sir Gardner Wilkinson's conjecture that Amenoph III. belonged to that foreign race, and the fact that two (at least) of his sons held their religion renders this still more probable. After the death of Amenoph III. the foreign chiefs became very powerful, and succeeded in gaining possession of Egypt and Ethiopia, and holding those countries for some years. Their kings are found in Manetho's list, between Orus and Rameses, of the eighteenth dynasty, and since the former king destroyed their monuments they must be reckoned as before him; but they were after Amenophis, his predecessor, consequently they must be placed between these two kings, or reckoned as contemporary with one or both of them, but mostly with Orus, since his monuments are few, and thus indicate a reign much shorter than that assigned to him by Manetho, namely, thirty-six years and five months, or thirty-seven years. To class the kings of the sun-worshippers in their proper order is a work of great difficulty, though much has been done by Sir Gardner Wilkinson and M. Prisse towards effecting this desirable object.

The monuments erected by these foreigners must have been considerable; but few now remain, and these have suffered severely from the hatred which the Egyptians bore to this people. Their most remarkable records are to be found in the sculptures of the grottoes of the ancient town of Psinaula and in the sculptures on the hills near Ashmooneyn, the old Hermopolis Magna, and in some sculptures in Ethiopia. From these we obtain a general idea of their religion, which was a simple form of sun-worship. In their religious inscriptions we find the sun represented as a disc with numerous rays issuing from it, each terminating with a human hand, one of which presents to the worshipper the symbol of life. The names under which these people worshipped the sun are Aten-ra or the solar disc, that is the visible sun; Mui-ra, the brightness or rays of the sun; and Ra or Phra, the solar principle or power supposed to reside in the sun. It is well known that sun-worship was practised in ancient times by many powerful nations of Asia, by some of the Chaldeans, by the Medes, Persians and Bactrians, by the Massagetæ, a tribe of the Scythians, by the Phœnicians and by some of the Syrians. Among all these nations the sun appears to have been the principal object of worship, and among some of them the sole god. It is interesting to compare as much as we know concerning the religion of the sun-worshippers in Egypt with the Chaldean oracles of Zoroaster, as given by Cory in his "Ancient Fragments." Although generally of late origin, they certainly contain many of the principles of the old religion of Zoroaster. Thus, for example, we read:—

It becomes thee to hasten to the light and rays of the Father,
From whence was sent to thee a soul, endued with much mind.

A sentence which forms a curious comment on the worship of the foreigners in Egypt as represented upon their own monuments, and similar instances might be multiplied, but I shall only notice the regal character of the sun and another remarkable point. Zoroaster and his followers generally speak of one deity, though it is evident that they had a triad or triads, and in like manner, though the hieroglyphic inscriptions of the sun-worshippers uniformly represent but one object of adoration, yet in two instances mention is made of "the suns." Now, from the different names given to the god of the sun-worshippers, it is obvious that they adored one god whom they considered as resident in the sun and operating through its rays, and yet that they worshipped the principle through the medium of the sun and its vivifying rays. These evidently correspond to the fire, sun, or light and ether of the Zoroastrian triad, originating from a monad. The only one of these correspondences that appears at first sight strained is that of the third person of the Zoroastrian triad, ether, with the principle resident in the sun, but the objection is removed when we remember that the ether of Zoroaster corresponds to the soul or spirit of the universe, of several of the ancient philosophers, whose principles are well known. How interesting it is to see in the earliest monuments of Asiatic nations yet known the

first records of that religion which so widely prevailed in Asia for so many ages, and which is not yet extinct.

Precisely how and when the sun-worshippers were expelled from Egypt does not appear; though it cannot be doubted that Orus, the Har or Hor, of the monuments, was the king who overcame them, for it has been ascertained that he built a propylæum at Thebes from the materials of former edifices erected by the foreign kings, and this, joined to the fact of the very frequent erasure of their names by the Egyptians, even in private tombs, renders it most probable that their expulsion was effected by force.

After this time no very remarkable event appears to have happened until the accession of Sethee I., the Sethos or Sethosis of Manetho, and first king of the nineteenth dynasty. In the sculptures on the north wall of the great temple of El-Karnak, at Thebes, are several already supposed to refer to the expulsion of a shepherd-race from Egypt. From the inscriptions which accompany them, we learn that King Sethee expelled a race of shepherds "of the land of Shasu" from the city of the Lion, in the first year of his reign. It is not certain whether the city of the Lion is Leontopolis or Thmuis, for Thmuis has the same signification in Coptic as Leontopolis has in Greek. However, I think it more probable that it is Thmuis, because that town preserved the original name.

Manetho, in his relation of the events of the reign of Sethosis, as cited by Josephus, speaks of that king as Ægyptus and of his brother Armais as Danaus, and relates at some length the offences of Danaus and his usurpation. Herodotus, in a similar relation, confounds Sethee with Sesostris. It is obvious that the supposition that the flight of Danaus took place early in the reign of Sethee is repugnant to all the systems of Greek chronology derived from the statements of the Greek writers; but the fact of Manetho's putting forth that idea was probably occasioned by his concluding at once, from the similarity of the Egyptian account to the Greek traditions concerning Danaus, that Armais and Danaus must have been the same person as Herodotus had concluded before him.

It only remains to notice the account I have already mentioned of a great shepherd-invasion in the time of Menptah, or Menphthah, the son and successor of Rameses II. Josephus, who cites Manetho's account of this occurrence, expressly says that Manetho did not take it from his ancient records, but, "as he himself confesses, from certain fabulous compositions of uncertain authorship." This account is evidently a confused tradition of an invasion of the Shepherds during the times of the eighteenth or nineteenth dynasty, in which those foreigners, as coming from Jerusalem, are supposed to be the Jews. The tradition may be thus briefly stated. In the reign of Amenophis, the son of Rameses, and father of Sethos-Rameses, who is thus identified with Menptah, the son of Rameses II., and father of Sethee II., all unclean persons were sent out of the inhabited part of Egypt to work in the quarries; and on their complaining of the severity of such treatment, they were allowed to occupy the city of Avaris. Having thus obtained a place where they might easily revolt, they renounced their allegiance to Amenophis, chose a priest of Heliopolis as their leader, called in the Shepherds who had formerly possessed the country from Jerusalem, and with their assistance made war upon the Egyptians, while Amenophis, terrified at a prophecy, withdrew with his army to Ethiopia. But at the end of thirteen years the king and his son returned from Ethiopia, and drove out the unclean people and Shepherds. It is added that it was said that the priest who ordained their polity was Osarsiph, a Heliopolite, whose name when he went over to these people was changed to Moyses (Moses). It is quite unnecessary to refute the application of this account to the sojourn and exodus of the Israelites; though it is difficult to ascertain when the event happened on which the tradition is founded. It may refer to the shepherd-expulsion in the time of Sethee I., or to an event which perhaps happened towards the close of the reign of Menptah, which latter conjecture is not improbable, since two usurping sovereigns reigned between Menptah and Sethee II.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE ordinary meeting of the Institute of Architects was held on Monday evening, Mr. F. C. Penrose, president, in the chair.

The President announced that Mr. James Brooks had been nominated as royal gold medallist.

Value of Simplicity in Architecture.

MR. HALSEY R. RICARDO read the first paper on the above subject. Living architecture, he said, is that which answers the requirements of the day. The requirements might be modest and sensible and the architecture would be beautiful and strong; they might be affected and individual, and then the architecture would probably be paralysed; they might be extravagant and vulgar, and the architecture would be violent and vulgar in response.

Mr. BASIL CHAMPNEYS read the second paper, in the course of which he said his remarks would have special reference to churches and country houses. Simplicity was a note of highest art everywhere and in all its branches. Reticence had been as obviously a characteristic in English art as in manners. In the fourteenth century, when foreign art was developing into vagaries and extravagances, the invention of Perpendicular held eccentricity in check in this country. The idea that simplicity in architecture was found to be in an inverse ratio to inventiveness was as dangerous as it was false. If necessity were the mother of invention, simplicity might truly be said to be the daughter of inventiveness. From first to last the law held good that every building to be a work of art must originate in one central idea, and that to this idea the inventive powers must be strictly subordinated, as it was better to apparently fail in inventiveness than actually to fail in unity and keeping. Unity and beauty should be the sole aims the artist allows himself to be conscious of. Originality he would never succeed in suppressing if it was present, or in generating it if absent. In the design of every building the primary problem was to fulfil certain definite practical requirements according to established constructional laws, and it was in the spirit in which such problems were met that good architecture mainly depended.

Mr. W. D. CARÖE read two papers, one by the President and another by Mr. Ince. A discussion followed, in which Mr. Wm. White, F.S.A., Mr. Primrose and others took part.

On the motion of Mr. STATHAM, seconded by Mr. ALMA TADEMA, a vote of thanks was passed to the authors of the papers, and the meeting adjourned.

EDINBURGH ARCHITECTURAL ASSOCIATION.

A MEETING of this Association took place in the Royal Institution, Mr. W. W. Robertson, the president, in the chair. Six gentlemen were admitted to membership, and two nominations were given in.

Mr. Percy Fitzgerald, F.S.A., made a communication on "Adam Architecture in London." Having suggested that there were at present symptoms of a revival of interest in the work of this illustrious family of architects, the lecturer proceeded to deal in considerable detail with the architecture of Robert Adam, whom he described as "the flower of the flock," and a man of extraordinary versatility, dramatic power and ability. His style was inspired by Diocletian's Palace at Spalato, with all the peculiar incidents of which he became permeated. On Adam's return to this country, the lecturer showed how extensive his practice became, giving it as his opinion that no other architect ever enjoyed so large an amount of remunerative work. In London alone it was almost incredible the number of buildings he set up. As to his principles of style, one of the most outstanding features was his marked individuality, Adam putting his stamp on everything he did. His exact sense of proportion, his great care as to the minutest details, and his singularly refined taste in various directions were notable characteristics of the man. The lecture was illustrated by nearly eighty limelight illustrations of Adam's handiwork, these forming a most interesting exhibition.

Mr. Fitzgerald's remarks were very attentively listened to, and frequently applauded.

Dr. R. Rowand Anderson, in moving a vote of thanks to the lecturer, said there was no doubt that the architecture of Adam was beginning to have its weight in the architectural study of the rising generation of architects, and they were fortunate in Edinburgh in possessing some of his very best examples. The Register House, to his mind, was the finest thing they had in the city. At the same time, he thought the father's work was a much more vigorous type of work than the sons'.

Professor Baldwin Brown seconded the vote of thanks, which was cordially passed.

HOLYROOD ABBEY.

ON Saturday evening Mr. S. H. Capper, architect, delivered a public lecture on "Holyrood Abbey," in connection with the Old Edinburgh School of Art. Mr. J. R. Findlay, the chairman, at first expressed regret that the Royal apartments in Holyrood Palace, which had very considerable architectural interest, were not open for public inspection. Many of the Royal palaces abroad were so open, and at Windsor the State apartments were regularly shown to visitors, except when the Queen was in residence there. He could not see why the rooms in Holyrood Palace should be closed except to a few favoured people who were invited as guests by the Lord High Commissioner. If the members of Parliament for the city and the municipal authorities exerted themselves a little, the rooms, he thought, might be opened to inspection by the public. He would never for a moment expect to see through Balmoral or

any private residence of the Queen, but Holyrood was not a private residence of the Queen, but a palace belonging to the people. Further, he thought that the gardens at the palace ought to be opened up and people allowed to walk there. In London thousands of pounds were spent on the Royal parks every year; a couple of hundred pounds would keep the Holyrood Gardens in order, and they would be a delight to thousands of people.

Mr. Capper explained that he was to deal with Holyrood Abbey as distinct from the palace, and showed, with the help of limelight illustrations, how fragmentary were the remains of the original building. He afterwards had thrown upon the screen pictures of a number of well-known ecclesiastical buildings in England, with the view of conveying to the audience some idea of the parts of the abbey church that have been swept away. In reference to the history of the church, he recalled the legend of King David and the stag, but pointed out that it was not till after the year 1400 that mention came to be made of it in connection with the foundation of the abbey. Mr. Capper subsequently spoke of the leading characteristics of the building from an architectural point of view, incidentally saying that he shared the hope of the Chairman that the palace gardens would soon be open to the public; and, in concluding, he reminded the meeting that two districts of the city owed their names to the existence of the church of Holyrood—the Grange, which came to us from one of the barns erected by the clergy of the abbey in ancient days for storing their tithes of corn; and Canonmills, so-called because there was situated in the old days on the Water of Leith a mill for the grinding of the corn of the canons of Holyrood. The lecture was made the more interesting by reason of the series of beautiful slides which were shown on the screen in illustration of the subject.

THE MEDIÆVAL MANOR HOUSE.

A LECTURE was delivered on Tuesday before the members of the Thoresby Society, in their room at the Albert Hall, Leeds, by Mr. F. W. Bedford, on "The Mediæval Manor House: its Architectural History." He remarked that very few manor houses were built during the twelfth century. The Normans built themselves fortresses in different parts of the country, but the land had not been sufficiently subdivided to call the manors into existence. From what examples we had, however, we found that they were generally built on a universal plan of a large hall with a chamber or chambers adjoining, and this formed the basis on which all the manor houses were built up to the end of the fifteenth century. The number of chambers was increased and other alterations in their disposition took place, but still the large central hall formed the nucleus of the plan. In most examples the hall was on the ground floor level, and was used by the owner and his followers for both dining and sleeping. Nearly all the examples of the Domestic architecture of the thirteenth century were built during the reigns of Henry III. and Edward I. A great many manor houses were built at this time, but they still kept the same general arrangements in plan as in the preceding century. The customs and manner of living remained the same, and so no great alteration was needed. In the fourteenth century a great development took place in Domestic architecture. To this period belong the finest domestic and collegiate buildings we have, as the colleges of Oxford, Cambridge and Winchester, Gainsborough Manor House, Wingfield and Haddon Hall. The large hall still continued to be the dominant feature in the plan, but it was less used by the owner and his guests. In fifteenth-century manor-houses the first thing that struck us was that the hall continued just as before, excepting that in many cases its size had been reduced in proportion to the increase in the number of other rooms—withdrawal-rooms, dining-rooms and bedrooms. Since the end of the fifteenth century we have made very little alteration in the plans of our country-houses. During the Renaissance periods—the sixteenth, seventeenth and eighteenth centuries—they became more formal in plan, but did not differ materially. Great improvements of course have been made since in the practical fittings, sanitary arrangements, heating and so forth, but a fifteenth-century house was often quite as convenient, as comfortable and pleasant to live in as a modern house, and generally far more dignified and beautiful. The lecture was illustrated by means of numerous ground and upper floor plans of manor houses. After some discussion, in which Mr. T. Ambler and Mr. J. Lister, Shibden Hall, Halifax, took part, a vote of thanks was passed to Mr. Bedford on the motion of Mr. Witherby, seconded by Mr. A. E. Kirk. Colonel Wilson presided.

The Greenock School Board have invited ten architects to send in plans in competition for a school to accommodate 1,000 children, 500 infants included, and the cost is strictly limited to 10,000/.

An Inquiry into the Real and Alleged Defects of Flueless Gas Stoves.

SIR,—A case has recently come under my notice, where an "opinion" has been obtained, and a number of flueless chancel stoves, with atmospheric burners, have been condemned after four years' constant use in a London chapel. The statements made against these are so plausible and neatly put, that they require consideration before their utter fallacy and incorrectness can be seen, and the facts are of very considerable importance, as they prove beyond question not only the conditions caused by flueless stoves, but also the comparative impurities from different sources and the danger of attending crowded meetings.

The alleged objections to the flueless stoves are that "they generate thousands of cubic feet of carbonic acid, which is dangerous and unhealthy."

"The gas when burning pollutes the air with its own organic impurities."

"That the oxygen of the air in the room has fed the gas-heaters."

"That the sensation of welcome warmth prevents the badness of the atmosphere being at once recognised, but the carbonic-acid gas will produce its effect on the congregation."

"That the method of heating renders the air quite unfit for breathing."

The inquiry into these alleged defects entails a complete examination into the conditions under which the stoves and the building are used, and to prevent any personal bias I give the authorities for all statements, selecting only those whose reputations are accepted by experts as being unquestionable.

The building has floor surface of 47 feet by 41 feet by 1927·09 feet. The average height is 24 feet, and the area is therefore 46,248 cubic feet. The average congregation is 600. The floor surface is, therefore, $3\frac{1}{2}$ square feet for each person, as against the 8-feet minimum for Board schools for infants. The cubic area for each person is 81 feet as against 240 feet minimum for a registered common lodging-house (these data are taken from Dr. Whitelegge's text-book on "Hygiene and Public Health").

The building is lighted by ninety-six gas-burners; the consumption of each is not given, but taking it at the low average of 3 cubic feet, the total gas consumption will be 288 cubic feet per hour for lighting only.

The eight "chancel stoves" for warming burn a maximum of 15 cubic feet per hour each, a total of 120 cubic feet, but it must be noted that these are never used whilst the congregation is assembled; they are lighted for some hours in advance only.

Dealing first with the carbonic acid, the amount of this evolved from the combustion of coal-gas has recently been redetermined by the *Lancet* commissioners to check previous results (see *Lancet*, January 5, 1895), and the amount per cubic foot of gas is 52 cubic foot, practically one-half the bulk of the gas burnt. The alleged thousands prove to be a total of 61 cubic feet per hour.

Expired air from the lungs of an average person contains (as determined by Pettenkofer) 4·5 per cent. of carbonic acid, and each adult whilst awake gives off 8 cubic foot per hour. The 600 persons would therefore involve 480 cubic feet carbonic acid per hour, the warming stoves 61, and the lights 147, a total of 688 cubic feet per hour; allowing for absolutely no ventilation the contamination of the atmosphere in one hour would be in carbonic acid by the congregation 1 in 100 parts, by the lighting 1 in 331, and by the heating stoves 1 in 797—total from all sources 1 in 70, equal 1·43 per cent., less than one-tenth of this being formed by the heating apparatus.

The normal quantity of carbonic acid in the air is 3 per 1,000, but as shown by the careful and exhaustive experiments of Dr. Haldane and Dr. Lorrain Smith (see British Association report), if present in 100 times this amount, or 3 per cent., its presence is inappreciable except by chemical analysis, and its action is simply that of a diluent, like the nitrogen which constitutes four-fifths of the atmosphere. It is therefore evident that, in the complete absence of ventilation, the carbonic acid formed by every source is inappreciable.

The statement that the gas when burning pollutes the air with its own organic impurities is very simply disposed of. Gas is universally used for sterilising by all who are engaged in bacteriological research; the temperature required for sterilising is 400 deg. Fahr., and 1 cubic foot of gas a burning will raise 144 cubic feet of air to this temperature. Its action is therefore precisely the reverse of what is stated; and again allowing for no ventilation, and no absorption of heat by the walls, the gas burnt for lighting and heating would actually

sterilise and destroy the whole of the organic impurities evolved by the persons present. This is not the case, for the very simple reason that almost the whole of the heat is immediately absorbed by the walls of the building. By direct experiment it has been shown (see "Coal Gas as a Fuel") that 1 cubic foot of gas in burning will heat 2,460 cubic feet of air 20 deg. Fahr., and if the heat were not absorbed by the walls, the consumption of 10 cubic feet of gas would raise the temperature of the room 10 deg. Fahr. As a matter of fact, until the walls rise to the same temperature as the room they absorb at once from the air most of the heat evolved, and this explains the reason why large and powerful stoves require so long a time to produce an effect in a large building, a fact well known to all who have to deal with heating arrangements of this class.

Where the Heat goes to.—A number of careful experiments show that, in average practice, for every 1,200 square feet of wall surface, in a room with ordinary ventilation, 660 British thermal units of heat are required for every 1 deg. Fahr. rise from normal, and allowing for the usual ventilation of a complete change of air every twenty minutes, 75 per cent. of the heat is lost by the walls and ceiling. If the air is changed only once every forty minutes and the same temperature kept, 87½ per cent. must be lost through the walls and ceiling. These figures will vary with every building, but as they are taken from careful experiments in rooms which are kept at the same temperature night and day constantly, it is clear that under any possible circumstances the actual warming of the air is almost a negligible function as compared with the loss by conduction through the walls. The system of calculating the heating power by the cubic area is one which needs to be discontinued, as being totally at variance with working results. No doubt many who are accustomed to exact physical research will at once question my figures as to the absorption of heat by air, which varies enormously with the quantity of moisture present; but the answer to this is simple—the results given are those of average working for long periods in actual practice, and lower than the theoretical calculated averages; they are practical working figures which naturally come out lower than the theoretical ones, as they include sources of loss which cannot be avoided. This problem is a most complicated one, as it is affected not only by variations in ventilation caused by differences of inside and outside temperatures, but also by the heat evolved by the occupants of the buildings and the natural differences in the mean temperatures inside and out, which affect the loss by walls and other sources of error. In one case the required heat for a large building came at 277,400 British thermal units in twenty-four hours above the calculated requirements. This error was caused by the temperature at which the contents of the place (a beer-bottling stores) were brought in and removed; the surplus heat had been absorbed by the bottles and their contents.

"That the sensation of warmth would probably prevent the badness of the atmosphere being recognised," is precisely contrary to facts. Warmth always increases the smell from organic matters. Nothing more need be said on this subject further than to refer to the experiments of Dr. Morin at the hospitals of Beaujon and Vincennes, and M. Peclet at the Mazas prison and the school at Grenelle. These are sufficiently quoted in "Box on Heat."

Ventilation Required.—This varies greatly, but if the average results are accepted as given in "Whitelegge's Hygiene," and also in "Box on Heat," at least 500 cubic feet of fresh air per hour will be required for each person, with about one-tenth added for lights, making a total of 550 cubic feet for each person. The 600 would therefore require 330,000 cubic feet of air passing through the building per hour, i.e. an entire change of air every 8½ minutes, an obvious impossibility, except with a powerful forced draught of warmed air; and taking the average figures given by Whitelegge as regards natural ventilation, it is evident that the building is enormously overcrowded, a change of air every twenty minutes being the maximum under ordinary circumstances without excessive draughts.

I now come to the actual cause of the offensiveness of the atmosphere of the room, and this explanation applies more or less to all public buildings. The presence of carbonic acid, as exhaled from the lungs, is merely an indication of the presence of other and dangerous matters which accompany it; when exhaled from living beings the effect of these is, by our technical persons, ascribed to the inert carbonic acid. Dr. Whitelegge's report on this point is clear. The moisture formed during the combustion of coal-gas is perfectly sterile and does not lend itself to the cultivation of bacteria; the moisture evolved by each person in the room will average 2½ ounces per hour, two-thirds of this from the skin, one-third from the lungs. Therefore, 93 lbs. weight of water per hour is discharged by the 600 persons assembled, and in the absence of most efficient ventilation, a large proportion of this condenses on the walls. The expired air contains much organic matter, which is readily absorbed by the moisture present. It promotes the growth of organisms, has a foetid smell, and meat, milk and other food in contact with it readily becomes tainted

(Whitelegge). There can be no doubt that the walls of the buildings are covered with organic matter and bacteria, and that the congregation is far too large for safety to health. The action of the heating apparatus, as regards the purity of the air, is so exceedingly small as compared with the causes that it may be entirely ignored. The only possible emanations from the gas flames are a minute trace of sulphur which may be appreciated occasionally, but which cannot in the maximum possible proportion be considered other than harmless. The other is carbonic oxide, which, if formed, is undoubtedly dangerous; but the experiments and analysis of Professor Vivian B. Lewes show that this is not formed when gas is burnt in a clear unobstructed flame. A faint trace of this gas has been suspected from the Welsbach incandescent lights, and much capital has been made out of this by the electric-lighting companies, but the recent researches of the Lancet Commission show this statement to be entirely without foundation.

I will now deal with the real defects of flueless gas stoves, and it is very curious that none of these were mentioned directly or indirectly in the "opinion."

First and greatest is that they do not assist the necessary ventilation of the room; this defect they share with the hot-water pipes, and to a greater extent, because with the latter it is possible to make perforations in the wall behind the pipes, the incoming air being slightly warmed whilst draughts are prevented.

Second, this form of stove, to prevent the formation of carbonic oxide, must have flames which are clear and unobstructed by incandescent solid substances, which give a large proportion of radiant heat, an absolute necessity in rooms where persons are to be seated in comfort for any length of time. Heat radiating from glowing coals or other incandescent material passes through the air in direct lines, without modifying its temperature to any important extent. Radiant heat coming in contact with persons, furniture, or walls, imparts warmth to these whilst leaving the air comparatively cool. If we have moderately cool air to breathe, whilst our bodies are kept at a comfortable temperature, it is more healthy than if we have to breathe hotter air in the endeavour to obtain the same degree of comfort.

Convected (or conducted) heat by warm air has one most serious objection, that the warm air has a tendency to rise to the upper part of the room, and the upper strata becomes warmer than the lower, the feet are kept colder than the head, and the consequence is, unless circulation is assisted by moving about, a liability to cold feet and a consequent headache, the cause being, not as is usually supposed impurity of the air, but improper and unnatural distribution of the heat. In bedrooms, when the body is at one level, this objection does not exist, and there is little doubt that in this case a flueless stove will be unobjectionable, the actual pollution of the air by a flueless stove, which consumes the gas perfectly, being so small that it does not need consideration if a reasonable amount of ventilation is secured by other means. I do not wish to make myself a champion for flueless stoves. The objections, although negative and purely mechanical, are decided, but in many cases the choice is between these and a dangerous degree of cold, and it is well to know what the objections really are so that they can be modified and guarded against. The results given show clearly that, so far as actual pollution of the air is concerned, a good flueless stove is less objectionable than the presence of an extra person in a badly-ventilated room. To those who have to use a flueless stove in a room, let me suggest a simple experiment imported from the land of stoves, *i.e.* America. Put the feet up to the level of the head, so as to get them out of the cold air on the floor, and all symptoms of discomfort will disappear. When an American lifts his feet up from the cold air-bath on the floor of a room heated by a close stove, he only obeys a law of nature which enjoins him to keep his feet warm and his head cool as far as possible.

The last objection to flueless stoves is peculiar to both these and paraffin-oil stoves. They are the only sources of heat which do not dry the air of the room they are used in; this is no objection in ordinary living rooms, but is a decided one in shops where polished steel and similar goods are kept, and the balance for or against must be taken after consideration of the conditions needed. It would appear that where no flue is available they have a distinct advantage for many purposes, but their use is limited by objections which exist under certain conditions. It is evident that the carbonic acid and pollution of the air theories which are commonly held have no basis whatever in fact, and the objections are more mechanical than chemical.

The problems of heating and ventilation are usually calculated, even by architects and heating engineers, on the same basis, *i.e.* the cubic air space enclosed. This is perfectly correct for ventilation, but it has not the slightest relation to the heating power required. As already shown, the heat absorbed by air is so infinitesimal in quantity that it may be neglected; and the only matter needing attention is the heat absorbed by

the walls, roof and floor. As these bear a very close relation to each other in most buildings, it is only necessary to take the wall area as a basis; and the results of numerous experiments on both a large and small scale show that in an ordinary building without skylights, nearly one-half of one British thermal unit is absorbed by each square foot of wall-surface per hour for every 1 deg. Fahr. rise over the normal temperature maintained after the first warming up is complete. The building in question has a wall-surface of 4,224 square feet, and for every 1 deg. Fahr. rise of temperature to be maintained 2,112 units of heat will be absorbed, *i.e.* the heating power of $3\frac{1}{4}$ cubic feet of ordinary 16 candle gas, or $32\frac{1}{2}$ feet for a rise of 10 deg. It must be noted that the actual consumption is nearly four times this, the preliminary heating up requiring the excess. If the temperature was once attained throughout the building, and the heating continued steadily day and night, the gas consumption would be reduced $32\frac{1}{2}$ cubic feet per hour for every 10 deg. rise over the normal temperature. Applying this method of calculation to a smaller room, say 10 feet each way, the heating power required would be fully five times as great for the cubic area, owing to the larger proportionate area of wall-surface, and this is undoubtedly the case in practice. This is an important point in the consideration of flueless stoves; the basis given for this in the chapel in question applies only to buildings of the same size, and the heating power required increases in direct proportion as the size of the building decreases.

It would appear that the use of properly-constructed flueless gas stoves in living rooms cannot be in any way injurious to health so far as any pollution of the atmosphere is concerned. That they are, under certain conditions, uncomfortable, is an undoubted fact, but so long as the conditions are known and guarded against, as far as possible, the objections have little or no existence. Many attempts have been made to equalise the temperature at different levels in rooms warmed by flueless gas stoves, but all have been more or less failures, owing to the very small proportion of pure radiant heat available, and the natural tendency of warm air to rise. Much can be done by the use of thick warm carpets and rugs, but not sufficient to entirely overcome this one defect, which exists also with hot-water pipes, warm air and paraffin stoves.

THOS. FLETCHER, F.C.S.

GENERAL.

The Annual Exhibition of works by students of the Birmingham Municipal School of Art is now being held at the rooms of the Royal Society of Artists.

The Aberdeen Artists' Society have published the results of the last exhibition, and it appears that it was the most successful exhibition ever held in Aberdeen both from the artists and the subscribers' point of view. Pictures to the value of 2,528*l.* were sold, being 1,000*l.* more than in any former year. The subscribers have increased to 463; the receipts at the door have also increased.

Mr. Arthur Pain, at the meeting of the Surveyors' Institution on Monday, the 18th inst., will read a paper on "Light Railways."

A Meeting of the Court of Governors of the University College of South Wales and Monmouthshire was held on Wednesday, when an influential deputation was arranged to wait upon the Chancellor of the Exchequer for the purpose of obtaining a grant of 100,000*l.* for new college buildings, which it is estimated will cost between 200,000*l.* and 250,000*l.*

Sir John Soane's trustees will on Monday next meet at the Museum, Lincoln's Inn Fields, to distribute the dividends which have accrued during the year from the sum of 5,000*l.* invested by Sir John for the benefit of distressed architects and the widows and children of deceased architects.

The Royal Scottish Academy on Wednesday elected Mr. Charles Martin Hardie and Mr. George W. Johnston as members.

Mr. J. S. Crawshaw, who has for several years past occupied the position of surveyor and sanitary inspector under the late Skegness Local Board and the present Urban District Council, has been elected surveyor to the Weybridge Urban District Council, at a salary of 200*l.* a year. There were upwards of two hundred candidates for the post.

The Athens correspondent of the *Standard* says:—The excavations which a party of German *savants* are carrying out on the site of the ancient theatre of Dionysus has resulted to-day in the discovery of a subterranean passage, through which the actors in old times used to pass up on to the stage. This is the only discovery of note that has hitherto been made in the course of these excavations, which are under the general supervision of Dr. Dörpfeld, the Principal of the German Institute at Athens. A similar passage, I may add, was discovered some years ago on the site of the ancient theatre at Eretria, in the Island of Eubœa.

The Architect.

THE WEEK.

WHEN the Charter was granted to the Royal Scottish Academy about four years ago, many sanguine people imagined that the narrow-mindedness which made that institution unique in Europe was likely to come to an end. That was not our view. We had seen as much of the working of the Academy as was possible for an outsider, and from familiarity with the effects we could realise the character of its causes. Articles which appeared in this journal a long time ago could now be reprinted as if they were inspired by recent malpractices. Now, as always, architecture is doomed to be the victim. When the Scotch architects opposed the Academy's Charter before the Privy Council, their chief contentions were that the scheme did not provide for a due proportion of the funds of the Academy being devoted to the promotion of art, and that it did not oblige the Academy to have a certain proportion, or any architects in its ranks. But in spite of the representations the Privy Council granted the new Charter, merely recommending, in terms which were regarded as equivalent to a command, that in future architecture should get its proper share of attention. Following upon this, the Academy took the first opportunity to elect a number of the leading architects as Associates. They accepted membership in the belief that the Academy had turned over a new leaf, and that as members they might soon be able to render some good services for their department of art which they could not do if they stood aloof. As Associates, however, they remained without any executive power whatever, and nothing could be done for architecture by the Academy till one or more of these Associates were raised to the rank of Academicians, which it was understood would be arranged at the earliest opportunity. The arrangement could only be accomplished by giving the new Associates precedence over men who had been many years in that rank, but this involved no injustice to the old Associates, because if the Academy had been doing its duty some of these Associates would not have been members at all, and the very architects now awaiting promotion would have been in their places at the top of the list. If the well-being of the Academy required some little self-denial on the part of painters and their friends it ought to have been displayed. The desired opportunity arrived last week, but it was neglected. Regardless of all that had been agreed upon, two painters were elected. The course adopted has damaged the Academy. It gives countenance to the old reproach that it is simply an institution manipulated by certain Edinburgh cliques for their own purposes, and that it is vain to hope that it can ever be made anything else. The effect produced on the public and all interested in art would have been entirely different if two architects had been elected. The prestige of the Academy would have been immensely advanced, and its influence as a national institution strengthened. The architect-associates, who were still anxious and willing to make the best of everything, would have been immensely encouraged, and would loyally endeavour to subserve the interests of the Academy. Now it is difficult to resist the conviction that Dr. ROWAND ANDERSON was right, and that a man who wishes to aid in advancing architecture had better withdraw from all connection with the Royal Scottish Academy.

THE judgment which was given a few days ago by Lord KYLLACHY respecting one of the large hydropathic establishments at Callander would appear to show that the responsibility of leaseholders is more onerous than in England. The action was brought by the owner of the ground. In 1881 he fued or let in perpetuity certain lands to the Callander Hydropathic Company. Among the considerations were that the buildings were to be insured for not less than 15,000*l.*, and in case of fire the parts destroyed were to be rebuilt, in order that the valuation should be kept up. The buildings cost about 40,000*l.* In 1885 the property

was acquired by another company, called the Callander and Trossachs Company. Eight years afterwards the buildings were consumed, and about 14,000*l.* for insurance was paid to the company. In the beginning of 1894 the place was sold to the Eagle Property Company, and in the course of the year it was conveyed to JOHN WILSON. The "superior" or ground landlord brought the action against all the owners for breach of the agreement to re-erect any building destroyed. One company after the other pleaded that their obligations came to an end with the transfer of the property, of which notice had been given to plaintiff. JOHN WILSON, in turn, contended there were no grounds for suing him. Lord KYLLACHY held that whatever might be the law in respect of rent or duties, the transference of a feu to a new "vassal" did not relieve the old "vassal" of his obligations. Accordingly, judgment was given against Mr. WILSON, the Eagle Property Company and the Callander and Trossachs Hydropathic Company. The plaintiff agreed to having a decree for the erection of buildings of the value of 15,000*l.* While it is easy to transfer property in the North it becomes evident that in spite of conveyances the obligations remain with the party who assumed them at first, although the subsequent parties are no less bound.

IT is remarkable to find Great Britain still surpassing most countries in the world in the extent and value of imports. A return has just appeared on the trade of Stettin. It appears the value of the timber exported to all parts of the world from that port in 1893 was 216,011*l.* 12*s.* More than one-half of it went to Great Britain, for the value was 120,359*l.* 4*s.* In other words this country is as good a customer to the Stettin merchants as the remainder of the world. Yet for one important item, viz. pinewood, the English market is closed to Stettin on account of the competition offered by Dantzic. The Portland cement trade would have been successful if it were not for some accidents in Stettin. A fire which arose in the Stettin-Bredon factory destroyed nearly the whole of the kilns. Another fire at the Stettin-Chamotte factory destroyed the upper factory entirely, and work had to be carried on by day and by night at the lower factory, by which expenses were largely increased. In some of the factories about 600 men find employment.

ROME has lost a patriarch by the death of FRANCESCO PODESTI, the painter. He was within five years of becoming a centenarian. Up to the last he was without bodily pain, and as for trouble the patriarch could hardly have known what it signified. PODESTI was a type of those Italian artists, who seem as if there was something of the antique faun in their composition. As long as there was sunshine and enough money to satisfy urgent needs he was happy. He was a native of Ancona. In his fifteenth year he came to Rome, and there he lived for the rest of his life. He was employed by the late Pius IX. to paint the frescoes of the Sala della Concezione in the Vatican. PODESTI also adorned one of the churches in Ancona with frescoes. But he did not limit himself to ecclesiastical subjects. Mythology, Italian history and literature afforded him numerous subjects. The titles of some of his pictures will suggest PODESTI'S range:—*The Toilette of Venus, Europa, Proserpina, The History of Bacchus, Diana and her Nymphs, Dante and Virgil, Giotto and Dante, Francesca da Rimini, Tasso at the Court of Ferrara.*

THE publication of Acts of Parliament seems to be now a necessity with architects and engineers. Under the title "Practical Guide to Sanitary Legislation," Messrs. J. A. ANGELL and J. G. MORLEY, who are engaged as borough engineers, have brought editions of various Acts relating to public health, water supply, gas supply, electric lighting and telegraphs, housing of the working classes, local government, highways, &c. Copies of the model by-laws are also appended. A volume of the kind was long required, and the editors have taken care to make it acceptable by borough engineers. It is brought out in an excellent style by the publishers, Messrs. KNIGHT & Co.

CHARLES MERYON.

SOME fifty or sixty years since there was a physician among us who might have served as the model for THACKERAY'S Dr. FIRMIN. Instead of the classics he preferred to employ art as a subject for discourse whenever it became necessary to make an impression at a dining-table. Neither representative of the healing art was a strict moralist, and both were compelled in consequence to depart from England. The amateur found a refuge in Paris, and there a son was born to him, whom he prized not more

how could a youthful misanthrope compel his hand to represent men and women? The old buildings of Paris were hard and cold, true stony-hearted stepmothers, but compared with living beings they seemed to him as sentient with sympathy. So he resolved to express his art by their aid.

How was it to be done? He had received some lessons in painting as a hanger-on in one or two ateliers. But to paint views of buildings it was necessary to have money to buy canvas and colours, and there was no fairy queen or charitable grande dame who cared a jot about MÉRYON.

OLD HOUSE IN BOURGES.

than the ashes of a cigar. That unfortunate being was CHARLES MÉRYON the etcher. There were a great many children in Paris who, like him, were evidence that paternal affection is not a necessary quality in the human constitution, but probably not one among them was so sensitive as the English doctor's son. If he had been endowed with physical strength he would have startled revolutionists by his desire to wreak revenge on the society which he believed was made up of men like his father. But he was a weak boy from birth, and his rage merely exhausted his frail frame. MÉRYON was endowed with an artist's power. But

There was no demand at the time for etchings, but the materials for producing them were at least cheap. Accordingly he commenced the production of plates of medium size, although his hand would be more at ease in working in a large manner; but to gratify his inclination he would need copper-plates and sheets of paper which he could not acquire. Only on one or two occasions was an opportunity allowed him to etch on a large scale. One of them was a commission from the Government to reproduce an architectural painting by a Fleming. The amount to be paid was 60*l.*, which seemed like a fortune to MÉRYON, whose

only food was sometimes a few fruits out of his patch of a garden. But the plate was never completed, for while he was at work on it MÉRYON was attacked by one of his periodical fits of insanity, and was carried off to Charenton.

There never was an artist whose work was more representative of the conditions of his life than MÉRYON'S. It was only natural that he should like to represent the demons who from Notre Dame seem to revel in anticipating the time when the respectable sinners will be all found out and handed over to them to receive their punishment. Or he shows the beautiful residence for the swifts made of the most delicate of tracery and sculpture. MÉRYON was very fond of introducing a crowd of them in his skies; perhaps he may have felt that nature was kinder to them than to himself. But whatever his subject, he is sternly true to it. He never glosses over real things. Has he to represent a long line of Paris quays, he becomes indifferent to the charge of monotony and will not show an inch of cornice or moulding in an imperfect state to gain variety. If a range of buildings has 200 square windows he will not allow his hand to suppress one of them. As if to suggest the insignificance of his fellow men, he commonly represents the few figures he introduces as insignificant and excited. In that way he helps to emphasise the majesty and calm of some of the fine buildings and engineering structures.

their efforts to gain recognition of his genius, were wasted on MÉRYON. His suspiciousness was increased by his privations. He imagined that his friends were really trying to puff him in order to gain money by speculations in his etchings. There was, however, no end to MÉRYON'S illusions. Like GERARD DE NERVAL, who resembled him in many ways, he was smitten with the charms of an actress, and although in neither case was there an amorous word spoken, MÉRYON believed he had poisoned his fair one and buried her in his little garden. Whenever he could assure himself the police were not watching, he spent his time in digging for her remains.

The calamities which befell CHARLES MÉRYON have had the effect of creating an interest in his etchings. But their intrinsic merits are so high there is no need of any extraneous circumstance to make them attractive in the eyes of those who can appreciate works of art for their methods. So many men have taken up etching since 1868—the year in which MÉRYON passed away—his work may appear to be lacking in qualities which are visible in the windows of every print shop. The plates of modern artists may show more elaborateness and richness of effect, but we doubt if any of them have been more successful in suggesting the character of the architecture of old Paris and some of the provincial towns than the son of the English doctor. By the kindness

VIEW OF APSE, NOTRE DAME, PARIS.

Whatever may be the subject, there is consistency throughout the plate. We may suppose that one represents five minutes' work, or five days', or five weeks' constant toil. But, whether the time was long or short, MÉRYON apparently continued in one mood while etching, and that is the more remarkable if we remember that he could not be always held responsible for his thoughts, words, or actions. Yet his work is as sane as the production of a machine.

MÉRYON wanted only food, raiment and a shelter. He offered his plates at a price corresponding with his modest needs. But the amateurs were indifferent to them. His first series of Paris, consisting of fifteen etchings, was published at thirty francs, and was a failure. A set is now worth a large sum, for MÉRYON in disgust defaced the plates. Soon afterwards it was demonstrated in the auction-room that MÉRYON'S work brought profit to the purchasers, but the unhappy artist found it was no less difficult to sell a plate. Strange to say, the praises of such influential critics as BAUDELAIRE, PAUL MANTZ, BURTY and GAUTIER were fruitless for him. BAUDELAIRE described MÉRYON as the true type of the finished etcher, in whose work the best qualities of the ancient masters was to be seen. It is melancholy to relate that, owing to his mental infirmities, all the praise of the few enthusiasts, all

of the direction of *L'Art* we are enabled to give reproductions of two of his etchings, viz. one of the views of Notre Dame, Paris, and another showing an ancient house in Bourges. They are part of the series exemplifying all classes of work which have made the publication famous.

ENGRAVED JEWELS.

WHEN we look at a collection of antique and Renaissance sculptured stones like that which is the great attraction of this year's winter exhibition at Burlington House, it is difficult to suppress the regret which arises over the changes in fashion and manners which have brought one of the most beautiful of arts into neglect. A thing of beauty, as every one now knows, is a joy for ever, and a man who possesses the tiniest Greek gem is endowed with a treasure which is enough to make him envied by all men. But few would now care to expend the money that would be required for the production of an imitation of that class of work in our day.

The history of engraved gems confirms the fact that art in all ages depended on utility. The primitive records suggest that in a remote age precious stones were not employed simply for their beautiful colours. Those, for

example, which MOSES records to have been engraved by BEZALEEL for the ephod of the high priest, owed their importance to the names of the tribes of Israel. We find also that other stones were precious because the temporary possession of one was a credential of the bearer's representative character. It is not impossible that among the reasons which led to the recent rejection of the Chinese envoys by the Japanese was the absence of one of the seals or rings of the Emperor. In old days an ambassador who was not furnished with a similar token of confidence would receive treatment as ungracious as befell the gipsy when he posed as a representative of majesty, as described in "Quentin Durward."

It is possible also that some of those jewels acquired a character which demanded reverence, as if they were in some mysterious way connected with the gods. CLEOPATRA may have set more value upon her ring which bore the portrait of BACCHUS than on those which represented her evergreen youth. Her lover, broad-browed CÆSAR, may have believed that he possessed the protection of VENUS as long as he wore on his finger the portrait of the goddess. His rival POMPEY suggested himself by having a lion holding a sword engraved on his ring, but he was compelled to succumb to the devotee of VENUS.

As time rolled on the real or imaginary virtues of jewels were forgotten. They were looked upon as mere articles of luxury, and men and women sought to possess a vast number of them. The Roman gentlemen, especially of the Decadence, exhibited so many they were at last unable to bear the weight of them. A dandy was compelled to have two sets of rings, one for winter use and one for summer. We may suppose that the metal work of the summer rings was of lighter weight and that the stones were removed from the winter rings. It became necessary also to have sham jewels, many of which are now equally prized with the rarest stones; they become precious by the beauty of the engraving. Imitations were especially needed in the days when jewels were worn not only on the fingers, the wrists and the neck, in the hair and as girdles, but were also employed to add magnificence to robes and to sandals. The Nepaulese prince who some years ago startled London and Paris by his diamond turban, carried a large quantity of paste, and in old Rome an arrangement equally economical was likely to have been employed. His diamonds were not engraved, but as well as can be made out from the descriptions of Roman luxury, a stone was not much prized unless it bore some emblem. The employment of engraved stones as a sort of *passementerie* could not fail, however, to deprive them of many of their old associations.

Christianity was not favourable to the ostentation that was expressed by jewels. But a use was found for them. A great many were taken for the adornment of reliquaries and church plate, shrines, &c., although the subjects represented were not always the most appropriate. St. Mark's, Venice, still preserves some ancient examples, and many remained in French churches up to the period of the Revolution. The Abbey of St. Denis was probably the richest in that way.

It may seem strange that ancient jewellery should be so employed. We cannot imagine the clerics were always ignorant of the significance of the subjects that were engraved. We suppose they considered it was by divine agency that paganism should in that way be made to serve the interests of the true religion. At least, we have no right to cavil at the taste which has preserved so many examples of ancient art. What is more, the gems are the best preserved of all the works by Greek hands. Time has abraded the surfaces of marble statues, ancient temples are ruins, but the infinitely little examples of ancient sculpture are almost in the same condition as when they were handed over to the amateurs who first purchased them. On that account it is possible that the portraiture of the gems is more faithful to the originals than any of the busts. The accuracy seen in some of the representations of statues which have survived creates the confidence that many figures are no less accurate, although we have no means of testing them.

We have to thank Florence for the revival of the interest in glyptic art. The far-seeing LORENZO DE' MEDICI not only was an enthusiastic collector, but he em-

ployed artists to execute similar works. He set a passion in his city. The Florentines could not well wear the garb of the ancients, but at least they could make use of their rings. GEORGE ELIOT is true to history when she represents TITO MELEMA having a passport to fortune in the gems which were entrusted to him. And old BARDO is described as wearing rings that were massive, as ROMOLA knew to her cost. As the supply of ancient examples was limited, and not adequate to the demand, it is no wonder in Florence, and afterwards in other cities of Italy, gem engravers arose whose works are hardly surpassed by the best of those of a later time.

The power to distinguish between ancient and modern work has attained with some connoisseurs the character of a science. As the scale of figures is small, a microscopic examination is indispensable. A knowledge of mineralogy is advantageous, for a good deal depends on the character of the stone employed. The polish which a stone acquires by centuries of attrition is very different from what can be obtained by a quick mechanical process. Some imitators have turned old forms of an inferior class into costly objects by working up the contours of the figures, the test offered by the character of the stone being in favour of the deception. It is not easy to imitate Greek figures of the best period, but imitations which are very weak gain strength when surrounded by inscriptions every letter of which is a faithful copy of an ancient example. Facility in imitating lettering enables names of artists to be given which become a bait to the unwary. Some authorities maintain that genuine gems should be either round or oval. But it is possible that many gems of which parts were broken were altered in shape to a rectilinear form at a time when the value of a curved outline was not recognised. Strange to say Renaissance gems are more thoroughly executed than genuine antiques. The scale being small the Greek artists imparted prominence to the principal figures, not only by their position on a plane, but by the elaborateness of the execution.

The collection in Burlington House is not very large, and all the gems are not perfect, but it affords excellent material for those who have only an elementary interest in the art. The opportunity should not be lost for studying them. The national collections may be far the finest, but objects that are always available are too often neglected. If the art is not popularly appreciated in England, it is not for want of specimens that are as fine as any to be seen in Europe.

CHRIST'S HOSPITAL.

ON January 4 last Messrs. Hollams, Sons, Coward & Hawksley wrote to Mr. Alderman Vaughan Morgan, treasurer of Christ's Hospital, on behalf of Sir H. W. Peek, explaining that there appeared to be a general opinion that the proposed removal to Horsham was undesirable, and offering the hospital 100 acres of well-timbered land at Wimbledon, with a frontage of about two-thirds of a mile on Wimbledon Common, on moderate terms. They added that Sir Henry Peek would be willing to entertain a proposal for payment of a considerable portion of the purchase money by way of permanent rent-charge, and that he was actuated rather by a desire to benefit the charity than to dispose of the property, which was obviously suitable for immediate building operations. To this Mr. R. L. Franks, clerk of Christ's Hospital, replied on January 9, stating that the offer had been submitted to the Council of Almoners, and that he had been directed to decline it. Messrs. Hollams, Sons, Coward & Hawksley wrote to Mr. Franks on January 18, complaining that no reason had been given for declining the offer, and adding that Sir H. W. Peek was prepared to sell the property at Wimbledon at the same amount per acre as was paid by the Mercers' Company, with the sanction of the Charity Commissioners, for the site of St. Paul's School at Hammersmith, and that he would, although he felt it to be a very undesirable property, relieve the charity of the property at Horsham for such sum as valuers mutually appointed, or their umpire, might fix as the value. He would also, subject to deduction of the value of the Horsham property to be thus acquired by him, accept payment of the whole of his purchase money by way of perpetual rent-charge, following the precedent sanctioned by Parliament for compensation to Lord Spencer from the inhabitants of Wimbledon. The firm added that this course would enable Christ's Hospital at once to agree with St. Bartholomew's Hospital in respect of a substantial portion of the Newgate Street site, payment for which would provide funds for the

requisite new buildings for the school, and, in the meantime, there would be two large houses in which part of the work could temporarily be carried on. To this Mr. Franks replied on February 6, stating that the letter had been read to the Council of Almoners, and he was instructed to reply that the Council, having unanimously decided to build the schools at Horsham, could not reopen the question. Sir Henry Peek, in another letter, says that he still hopes for the sake of the future of the school that a better site than Horsham may be obtained, and that he cannot understand the inertness of the Charity Commissioners in the matter.

EDINBURGH MEMORIAL TABLETS.

ABOUT a year ago, says the *Scotsman*, an anonymous donor presented to the Edinburgh Pen and Pencil Club a sum of 100*l.* to start a scheme for affixing memorial tablets to houses in the city which were connected with the history of distinguished literary men and artists. It was a condition of the gift that the great names first dealt with should be those of Scott, Burns, Adam Smith, David Hume and Henry Raeburn. The original proposal was afterwards supplemented by an offer from the same source to defray the expense of erecting a tablet on the house in Comely Bank, occupied for two years by Thomas Carlyle. Very satisfactory progress has now been made with the scheme. Tablets to Scott, Burns, Hume, Raeburn and Carlyle have been completed, and those to Adam Smith, Brougham and "Christopher North" have been ordered, and are in course of preparation.

The special committee of the club entrusted with the carrying out of the scheme resolved to treat each case separately, so as to make the design of the tablet harmonise with the architectural character of the building to which it was to be attached. They also consulted the proprietor or the occupant of each house both as to the design and as to the material of the proposed tablet. It is satisfactory to know that in nearly every instance their proposals have met with a most cordial response. In only two cases thus far have their efforts failed. On the other hand, the proprietor of the house in York Place which Sir Henry Raeburn built and occupied as a studio (Mr. William Bartholomew), not only welcomed the advances of the committee, but agreed to defray the additional expense of a design somewhat more ornate than that which the committee submitted to him.

The completed tablets may now be briefly described:—

Sir Walter Scott.—In this case the inscription, enclosed in a sunk moulding, has been carved on the stone of the house, 39 Castle Street ("Dear 39"), which Scott occupied for twenty-eight years, and in which he wrote most of his novels. The panel thus simply formed is over the middle window of the dining-room, and bears the legend—"In this house Sir Walter Scott lived from 1798 to 1826."

Robert Burns.—The house in which Burns lived during his first visit to Edinburgh was in Baxter's Close, but the window of his room overlooked Lady Stair's Close, which is further west. Baxter's Close has been swept away, but Lady Stair's Close is extant. The adjoining land, 479 Lawnmarket, was lately rebuilt in solid fashion, and the architect, without any idea of an ulterior use, left in his design a stone panel over the entrance to Lady Stair's Close. The committee obtained the permission of the proprietor to place in the panel thus opportunely left a bronze tablet bearing the following inscription:—"In a house on the east side of this close Robert Burns lived during his first visit to Edinburgh, 1786."

David Hume.—The great historian spent his later years and also died in the house at the corner of St. Andrew Square and South St. David Street. Indeed Burton tells us that the street was so named in humorous irony by a daughter of Baron Ord in honour of David Hume. The tablet, a handsome slab of red granite, has been placed on the St. David Street end of the house, and bears the inscription—"In this house David Hume lived, 1772-76."

Thomas Carlyle.—Carlyle lived for two years in 21 Comely Bank. On the front of the house a red granite tablet, very similar to the Hume tablet, has been placed, with the legend—"In this house Thomas Carlyle lived from 1826 to 1828."

Sir Henry Raeburn.—This great artist lived during his later years at St. Bernard's, to the west of Edinburgh; but he built the house 32 (formerly 34) York Place, and occupied the upper floor as a studio for several years. The tablet, which is of freestone, inserted between the first and second floors, consists of a palette over a massive wreath suspended from rosettes. The palette bears the inscription—"In this house, built by him, Sir Henry Raeburn painted from 1798 to 1809."

The other tablets for which arrangements have been made are those to Adam Smith, Lord Brougham and "Christopher North." The Adam Smith memorial will be placed in the Canongate at the head of Panmure Close, which leads to Panmure House, which the author of "The Wealth of Nations"

occupied for many years. The Brougham tablet will be placed in the front of 21 St. Andrew Square, where the great chancellor was born in 1778, and where he spent his boyhood. The "Christopher North" tablet will be placed on 6 Gloucester Place, where John Wilson lived from 1825 till his death in 1854.

The second group of Scots worthies to be attacked by the Pen and Pencil committee consists of Principal Robertson, Hugh Miller, Dr. Chalmers, Dugald Stewart, Lord Jeffrey, Sir William Allan, Dr. Gregory and Napier of Merchiston. Other groups have been arranged, and will be taken up subsequently as funds are provided.

The special committee of the Pen and Pencil Club charged with the carrying out of the tablet scheme includes Professor Masson, Dr. Scott Dalglish, Mr. W. W. Robertson, Mr. W. D. Mackay, R.S.A., Mr. W. W. Macfarlane and Mr. John Harrison, on the last of whom, as convener, the main burden of correspondence and negotiation has fortunately fallen.

IN AN EGYPTIAN TOMB.

HAVING seen an announcement that M. de Morgan, of the Ghizeh Museum, had found at Dashur the jewels of an Egyptian princess of the twelfth dynasty, "Amy Strachey" and her husband decided to pay a visit to Dashur, and the former contributes to the February number of the *National Review* an account of the journey. After dealing with the attractions and humours of the journey, and of their being lost and found in the desert, she goes on to describe the arrival at the tomb:—"Profound was my dismay when we arrived at a hollow in the sand and, descending it, M. Pierre pointed to a sort of well about 10 feet square (speaking very roughly) and said, 'Il faut descendre là.' The entrance to the tombs of the princesses is at the bottom of this mummy pit." "And to the king's chamber?" I asked. 'Egalement,' said M. Pierre, dashing my hopes with a polite bow and wave of the hand towards the pit. There are some terrors which are more powerful than the feminine fear of being thought a fussy coward, and to be lowered down a mummy pit about 40 feet deep was more than I could face. At that moment we were joined by M. de Morgan himself, and I told him my fearful anticipations. 'Go down, Pierre,' said he, 'and show how easy it is.' So a rope was simply attached to M. Pierre's waist; the end was held by four Arabs and without machinery or pulleys of any kind he was quietly dropped over the edge. I was not reassured in the least, and sitting down in the shade I said I would await for the reascent of the party." Hearing, however, that the tomb was a thing not to be missed, she plucked up courage to descend, and describes the visit to the princess's tomb and the king's chamber. The latter is the more interesting. "The height of the underground passage leading to it drops," she says, "almost immediately from just under 6 feet at the entrance to about 3 feet 6 inches, and towards the heart of the pyramid, where the rock is very rotten, the passage is shored up by the short wooden props with which we had seen the camels laden at the south pyramid. At last the gallery sinks to a mere hole to be crawled through. The heat was great. Just then an extinguished candle gave evidence of the quality of the air, for it proved impossible to light a match to rekindle it, and the glass chimney being taken from a petroleum hand-lamp carried by one of the men, the flame of this also went out, leaving the party almost in the dark. But M. Pierre promised fresher air in the chamber itself, and the rekindling of the lights was left till then. After proceeding for about 20 yards through this 2-feet high hole, the miner's gallery breaks into the ante-chamber to the king's tomb. The chamber, lined with Tourah limestone, is encumbered with heaps of earth and rubbish on the ground, while on the west side a narrow doorway gives entrance to the tomb itself. Here the same confusion reigns—the great sarcophagus of finely polished rose-granite yawns empty and desecrated at the end of the chamber, the royal mummy having long since perished, hastily snatched from its resting-place and cast aside in the eager search for gold. Strange irony of fate, which turned the treasure piously dedicated by the survivors to the use of the dead into the inevitable cause of the violation of their tombs. The whole of the king's chamber is lined with the royal rose-granite, strangely enough overlaid with a coat of whitewash. So also is the passage down which the funeral procession passed. About 6 feet high, slightly vaulted, and with the masonry finished magnificently, it opens from the north-east corner of the tomb, going due north for some way and then turning straight to the west. It is not possible to go down it far at present, as the debris of the wall by which the robbers broke into the tomb encumbers it still. It is on the sides of the deep doorway leading from the royal chamber to the ante-chamber that the figures left by the robbers are outlined. Imagine the hour, four thousand years ago, when, resting from the work of ransacking the tomb, one of the men daubed up these rough

portraits of his fellows on one side of the doorway. On the other side, the figure of the king of the robbers stands alone, crowned with the identifying head-dress. Some of the chief interest of the great king's tomb now comes from this rude fellow's scrawlings, 'for so the whirligig of time brings in his revenges.'

THE HELLENIC SOCIETY.

A PAPER was read by Mr. J. L. Myres on Monday on researches in Caria. The paper was, he said, the result of observations made by Mr. Paton and himself in 1893 and of others by Mr. Paton and a Greek friend in the autumn of 1893 and the early part of 1894. The ground covered was the country which bordered the Latmos Gulf. The northern part of the country was chiefly explored by Mr. Paton and the south by Mr. Paton and himself. The modern road from Miletus followed the ancient track from Miletus to Iasos, and traverses a dreary plateau which in ancient times smiled with the abundant olive, and in which they found an ancient oil press of classical type. They discovered considerable remains of Lelegian masonry quite untrimmed, but still solid. The site of Keramos was perfectly well identified, and they were able to verify passages in the 13th and 7th books of Strabo in which the tombs and other buildings of the Leleges were described. It would appear that this district ceased to be inhabited after the third century B.C., as there were no traces of pottery or other remains which could be ascribed to a later date. There was a conjectural identification of Burgasa from Strabo at a point between Halicarnassus and Keramos, and the remains were found of one or two marble buildings, but no inscriptions. No ruins were found near Miletus, but in the agora of Kos was a plane tree of immense age, which might have existed in classical times. Callisthenes, quoted by Strabo, identified Pedasa with the Leleges, and Strabo seemed to know of two Pedasas, and Mr. Paton's observations appeared to be confirmed by the language of Strabo. The Leleges had eight cities, of which six were incorporated by Mausolus with Halicarnassus. Other passages from Herodotus and Livy also throw light on the labours of the English scholars. They discovered a fine tower of præ-Mausolean Carian masonry and one portico 24 feet by 10 feet of præ-Mausolean architecture. The paper was illustrated by a number of photographs of the various sites explored.

ARCHITECT'S FEES.

A CASE was heard in the Southampton County Court in which Mr. W. B. Hill, F.S.I., surveyor, valuer and estate agent, Southampton, sought to recover from Joseph Kaphan, fried fish merchant, Canal Walk and St. Mary Street, the sum of 22*l.* 2*s.*, made up as follows:—To receiving (in September) instructions, taking measurements and memoranda, preparing plans, elevations and specifications for rebuilding, and submitting same to the defendant, 20*l.*; to preparing set of tracing and plans, and forwarding same with application to the Urban Sanitary Authority, 2*l.* 2*s.* It was stated by Mr. Lamport that the amount claimed consisted of the usual architect's charges for work done on the instruction of the defendant. At the time the defendant was under an obligation to carry out the repairs to the building in St. Mary's Street, and lay out a sum of about 800*l.* on the premises. The plans were prepared and sent to the Urban Sanitary Authority, but they were returned to be amended in some slight particulars. The plaintiff wrote to the defendant reporting the result of the submission of plans, and asked him to call so that alterations could be carried out; but Mr. Kaphan instead of going near the plaintiff had other repairs of a different character, having purchased the freehold in the meantime. The defendant had declined to pay these usual charges.

Plaintiff gave evidence in support of his case. In reply to Mr. Emanuel for defendant, he said he was trying to do his best for the defendant in the plans, and the Council sometimes made concessions. He could very easily alter the plans to meet the requirements of the by-laws, and would have done so free of cost.

Mr. Wheeler, architect and surveyor, having charge of that department for Mr. W. B. Hill, stated that the charges made were reasonable. He admitted that by the alterations of the plans two rooms would be cut off, but they could easily be put somewhere else.

Mr. Mitchell, jun., a member of the firm of Messrs. Mitchell, Son & Gutteridge, gave evidence as to the fairness of the charges made.

Mr. Lamport contended that an architect would not lose his fees because the authorities did not sanction the plans, and especially was this the case when the architect was prepared to rectify the plans. This was a point of great importance to architects.

Mr. Emanuel, for the defence, urged that it was a novel situation for a surveyor to say he had made a mistake in his plans; that he had prepared plans which were useless, upon which the borough authorities would not allow him to proceed, and that he should write to the defendant asking him to come and show him what he was to put right. It was the duty of the plaintiff to send plans which could have been acted upon. He also contended that this was a contract to do the plans and carry out the work for 5 per cent.; it must be taken as a whole, and was not divisible. He also pointed out that the place had only been painted, and defendant intended to build.

Mr. Lamport wished to know whether plaintiff was to wait for his charge until the defendant was in a mind to build?

Defendant gave evidence stating that the two rooms, which would be cut off by the alterations of the plans, were necessary to meet his requirements.

In reply to Mr. Lamport, defendant said he had been unable to build because he had become his own freeholder. When he had the money he intended to build, and would engage the plaintiff to superintend the carrying out of the work, but he would not pay anything on account.

William Henry Killick, assistant borough surveyor, spoke to the plans prepared not being in accordance with the by-laws, and if anyone persisted in building upon these plans there would be a summons issued, and an order could be got to pull it down.

Answering Mr. Lamport, witness said he did not remember one instance during the two years and a quarter he had been here where the committee had sanctioned less air space at the back or side than 150 feet. Witness, in reply to the judge, said the plans should have shown the drains.

Judge Leonard nonsuited the plaintiff, without prejudice to an action in the future if the defendant ignored the plaintiff in his carrying out the building.

Mr. Emanuel assured his Honour that the defendant intended to build, but was waiting for the money.

Mr. Lamport said he was sorry he must appeal, as it was an important case to architects.

TESSERÆ.

Ogham Inscriptions.

THE inscriptions in the Ogham character, as they stood originally, were with few exceptions read from left to right. Beginning from the lower part of the stone on which they were engraved, though not at the very extremity of it, they run upwards, and the line of characters is frequently carried on over the top of the stone and then down along another of its faces or angles. Some of the names on the stones are actually Latin. In general the names appearing on the stones are such as commonly occur in early Irish church history, sometimes however slightly modified in the attempt to give them a Latin form. That the alphabet is not a very ancient one is sufficiently manifested by the arrangement of the letters. The five vowels, *a, o, u, e, i*, are formed into a group arranged in that order, thus manifesting the art of the grammarian in distinguishing vowels from consonants, and again in dividing the vowels into two classes of broad and slender. It may be added that the steganographic character of the Ogham presupposes the existence of an older alphabet of the ordinary kind. A comparison of the Ogham alphabet with the Persepolitan and Phœnician alphabets manifests that the pretended relationship between it and them has no existence. The single fact of the Ogham inscriptions indicating an acquaintance with the Latin language might be considered sufficient proof that they are not remnants of a pagan civilisation anterior to the introduction of Christianity into Ireland. For whatever may have been asserted with respect to the influence exercised by Phœnician merchants or colonists upon the religion, learning and arts of Ireland, it has never been pretended by writers on the antiquities that there existed there, in the remote pagan times, any active element of civilisation derived from Roman sources. But in addition to this use of the Latin language in Ogham inscriptions, there are other circumstances relating to them which manifest their connection with Christian times and usages. A considerable number of the Ogham monuments bear crosses of different forms. In order to get rid of the obvious inference which this fact suggests, some of the antiquaries who maintain the pagan origin of the Ogham character have boldly pronounced the supposed crosses to be pagan symbols. Others have conjectured that the crosses were inscribed at a comparatively recent period on Pagan monuments previously erected. In reply to the former assertion, which is unsupported by anything like proof, it is enough to state that the crosses are undoubtedly Christian, being perfectly similar in form to those occurring on early Christian monuments in Ireland and elsewhere. The latter hypothesis fails to account for the presence of the cross on a stone inscribed "Marianus," that name being decidedly Christian. Moreover,

there seem to be not the slightest grounds for doubting that the crosses on many of the stones are of the same date as the inscriptions which they bear. If it be asked why these monuments do not all bear the sign of the cross, supposing that they all belong to the Christian time, it is answered that some of them, for what we know, may have been the monuments of Pagans, seeing that Paganism survived in Ireland for centuries after the coming of St. Patrick. But it seems much more probable that they are the sepulchral monuments of Christians, on which the cross was not placed, either for special reasons, having reference to the individuals, or because it was not the custom of the time or place. There are similar pillar-stones in Cornwall and Wales, undoubtedly Christian monuments, on which the cross is wanting. Another significant fact in connection with the use of the cross on Ogham monuments is their general occurrence in localities where there yet remain traces of ancient ecclesiastical or monastic institutions. It appears scarcely accidental that in four instances groups of Ogham stones, seven in number, should have been discovered together. It is not improbable that these were the grave-stones of monks, whom we know to have been in the habit of living together in companies of seven. The chief objection raised by those who assert the Pagan character of the Ogham monuments rests on the discovery of so many of them in the interior of raths. That this objection should have any weight, it must be assumed that the rath was a structure confined to the Pagan times, and employed by Pagans only. So far, however, is this from being true, that we have on record abundant proofs that rath-building was in use amongst the Christian inhabitants of Ireland from the time of St. Patrick down to the middle of the thirteenth century. Churches were built in raths, and raths round churches, no doubt for the purpose of securing protection for the persons and property of ecclesiastical establishments in unsettled times.

Character in Architecture.

When we propose to ourselves to design a building, the very first question that should present itself ought to be, what character will it be most fitting to impart to our work? For we may be well assured of this—that however exactly our building may be in accordance with the ordinances of architecture, whatever may be its merits as a composition, however unexceptionable may be its details, if the general character of the building be not in harmony with its purpose, a fundamental defect exists for which no amount of art will compensate. Whereas, if the character of the building be in accordance with its purpose and destination, a favourable impression is produced which reconciles us to many blemishes of detail. For example, the principal front of the Imperial Palace at Vienna—a building which has all the worst vices of the most corrupt German school—yet possesses in its well supported character the great redeeming merit of appearing really like what it is, a great imperial residence. The garden front of Versailles may be cited, on the contrary, as an architectural composition sadly deficient in character, with little claim to the attribute of grandeur beyond its enormous length, and but feebly suggesting the idea of a great monarch's residence. To seek for an illustration nearer home, take the Banqueting House, Whitehall, a building the architecture of which seems remarkably expressive of the festive purposes for which it was originally designed, and this illustration is the more instructive when we have regard to the manifest unfitness of the building in all its features, internal and external, to an ecclesiastical purpose. There never was a more grievous misapplication of a fine piece of architectural composition. This quality of character may be described as a consideration involving so much more of feeling and judgment than of abstract reason, or of what logicians term dialectics. It would, therefore, be a hopeless attempt to lay down definite rules for insuring propriety of architectural character. We have neither numbers nor figures nor words by which the relative merits or the essential attributes of art can be gauged or compared with mathematical exactness. We want, and shall never find, a golden mete-wand, which shall serve to reduce genius to a matter of calculation, or to supply an unfailing criterion of good taste. We may, however, safely say generally of a building, that its character is well conceived if the intelligent observer be at once impressed by the congruity of its aspect with its destination. An hospital should not look lugubrious, and statues of maniacs should not decorate the portals of a lunatic asylum, as was the case at Old Bedlam. That would be a gross misapplication of the principle; yet, in such structures as these there is a plain propriety which forbids the architect to admit an air of levity into his work, or to indulge in fanciful decoration. To give to a court of justice the riant air of a place of public amusement, or to give to a private gentleman's residence the aspect of an ecclesiastical structure, or of a crenellated fortress in the days of catapults and cross-bows, would be to commit a solecism which no abstract ingenuity of design nor antiquarian correctness could possibly justify.

Pre-Norman Architecture in Ireland.

The native or Celtic style, much anterior to the incursions of the Danes or the Norman conquests in Ireland, is seen in churches of small size, like a Roman basilica shorn of its apse; rude massive buildings oblong in plan, with triangular-headed small windows, pyramidal shaped doors and cyclopean or Pelasgic masonry. This and the following style occupied the interval between the fifth and sixth centuries and the year 1176. The early Scottish, Anglo-Saxon and French churches of the sixth century were all parallelograms. It is remarkable that the Greek oblong temple, composed of a nave and shrine, like the Temple of Jerusalem, also consisting of oracle and nave, 116 feet 3 inches by 37 feet 6 inches, and 58 feet 1½ inch in height, were both derived from an Egyptian original. The architect of the temple on Zion was of Tyre, a Phœnician colony; and while the legend of Cadmus, a Phœnician and the civiliser of Greece, denotes a correspondence between those countries, the commerce of Tyre with the western isles is boldly asserted by many writers. These early churches, rather oratories than capable of holding a congregation, range from 20 feet to 60 feet in length; they are aisleless, rectangular, have no apse, and are never found in a circular form; sometimes they are provided with a small chancel, and occur in groups. On Mount Athos, in other parts of Greece, and in Asia Minor, churches were usually built in groups of seven, in remembrance of the seven churches of the Apocalypse. The round towers are of this period, which lasted till the eleventh century, but are continued until the thirteenth century. Their form was adopted in consequence of the difficulty of obtaining cut limestone for the corners. Their purposes were various; they have been variously represented as serving for a belfry, a beacon, a treasury and a retreat for the priests. In the fourteenth and fifteenth centuries they were replaced by tall narrow square central towers. In the earlier towers the parapet is plain, with a range of holes instead of gargoyles for letting off the water; in later buildings there are stepped battlements resting on corbels. The Saints' houses, the beehive houses of Connemara and the oratory of Gallerus, are of "cyclopean masonry," built of masses of rock and vaulted with stone roofs, but the latter are of a later date, and are provided with chambers. In St. Kevin's, Glendalough, the lower structure is of the seventh century. The upper tunnel vault was provided with ribs, on which were laid the horizontal courses of the outer roof, which was built up straight to throw off the rain; this plan was also adopted in Cormack's Chapel, Cashel, built 1127-34. The vault, upper chamber and belfry are of the twelfth century. The cathedral of Glendalough is full of interest as one of the earliest Irish structures. The east window and south door, however, are of the beginning of the thirteenth century. In the succeeding style of native architecture, the roof became flattened, chevron mouldings were introduced, the arches received semicircular heads in place of triangular pediments or square lintels, windows became larger, and chamfered beadings ran round the inner arch, and the masonry was inferior. The peculiar cairn-like shaped door, formed of three stones, two jambs sloping upward towards a horizontal lintel, lasted throughout the various styles, and took its origin, like the round tower and cyclopean masonry, in the stubborn nature of the building material. Within the Pale the English introduced the Early English after the Norman style. But the early architecture of the isles, Northumbria and North Wales, bore a great resemblance to each other. Dublin appears to have been the architectural school of North Wales later.

The Rise and Fall of Spanish Art.

Among the most remarkable features in the history of Spain are the rapid growth and decay of her power. She first began to rank among the great kingdoms in the reign of Ferdinand and Isabella. Their great grandson, Philip II., was the acknowledged leader and protector of Catholic Europe. Under Charles II., great grandson of the second Philip, Castile had ceased to produce statesmen and soldiers, and Peru to furnish ducats, at least to the royal treasury. The monarchy was as feeble as the monarch; its star had run its course in little more than six generations, rising at the end of the fifteenth and setting at the end of the seventeenth century. This era was likewise the great period of literature and art in Spain. Growing up with her political greatness, they added lustre to her prosperity, and a grace and charm to her decline. During the Middle Ages, her taste and imagination had been embodied in the unrivalled multitude of ballads, sung by unknown bards, part of which the Castilian romancers still preserve, and in the magnificent cathedrals reared by nameless architects in her Christian cities, the songs and the shrines being equally tinged with the colouring of northern piety and oriental fancy. The reign of "the Catholic sovereigns" is memorable for the discovery not merely of a new continent, but of vast regions of intellectual enterprise. History, the drama and painting were revived in Spain in the same stirring age that sought and found new empires beyond the great ocean. Pulgar, the father of Castilian

history; Cota, the earliest forerunner of Calderon; Rincon, the first native painter in the Peninsula who deserved the name, were the contemporaries of Columbus, and, with the great navigator, mingled in the courtly throngs of the presence-chamber of Isabella. The progress of refinement during the first half of the sixteenth century was, perhaps, more rapid in Spain than in any other country. The iron soldier of Castile, the Roman of his age, became the intellectual vassal of the elegant Italians whom he conquered. Under the Emperor Charles V. the Iberian Peninsula, the fairest province of Ancient Rome, grew into the fairest colony of modern art. The classical Boscan and Garcilasso and the many-gifted Mendoza left behind them monuments of literature which might bear comparison with those of Italy, Berruguete and Vigarny, schools of painting and sculpture that Florence might have been proud to own. The odes of Fray Luis de Leon were excelled in strength and grace by none ever recited at the court of Ferrara, and pastoral Estremadura could boast a painter—Morales of Badajoz—not unworthy to cope with Sebastian del Piombo on his own lofty ground. During the reigns of the three Philips literature and art kept an even pace in their rapid and triumphant march. When Juan de Toledo laid the foundations of the Escorial, Cervantes was writing his early poems and romances in the schools of Madrid. The versatile Theotocopuli was designing his various churches in and around Toledo, and embellishing them with paintings and sculptures, whilst Lope de Vega was dashing off his thousand dramas for the diversion of the court. Mariana composed in the cloister his great history of Spain, whilst Sanchez Coello, the courtier and man of fashion, was illustrating the story of his own times by his fine portraits of royal and noble personages. In the reign of Philip III. Velasquez and Murillo were born, and the great novel of Cervantes first saw the light. Solis and Villegas, Moreto and the brothers Leonardo de Argensola, famous in history, poetry and the drama, were contemporaries of Ribera, Cano and Zurbaran, and with them shared the favour and patronage of the tasteful Philip IV. When Velasquez received the cross of Santiago, Calderon was amongst the knights who greeted the new companion of that ancient order. In the evil days of Charles II. Spain and her literature and her arts drooped and declined together. Painting strove the hardest against fate, and was the last to succumb. Murillo and Valdés, Mazo and Carreño and their scholars nobly maintained the honour of a long line of painters till the total eclipse of Spain in the War of the Succession. With the House of Bourbon came in foreign fashions and foreign standards of taste. Henceforth Crebillon and Voltaire became the models of Castilian writing; Vanloo and Mengs of Spanish painting. From the effects of this disastrous imitation painting, at least, has never recovered.

International Relations of Gothic.

The Gothic architecture of France is the elder sister of our own, and, if not more beautiful, possesses beauties and varied expressions of its own, which must ever secure to it the earnest love and devoted admiration of every student of Mediæval art. Our own architecture can hardly be correctly understood without a knowledge of that of France. Their origin, development and history are so linked and entwined together that without the knowledge of both they cannot be fairly studied or appreciated. France, too, took the first place in art, as in arms, amongst the nations of Mediæval Europe. Her art productions may therefore be viewed as the normal types of Gothic architecture, and there is a boldness and nobility of treatment about them which especially commends them to the most diligent study of the architectural student and workman. The Mediæval architecture of Germany and of Italy has claims only second to those of France. The period claiming the greatest amount of attention, at least in Northern Europe, may be roughly said to embrace two centuries, viz. the great thirteenth, and a moiety of the preceding and succeeding centuries; that is to say, from A.D. 1150 to 1350. Earlier and later periods must be fairly represented, but this interval contains the real vigour, the pith and marrow of Mediæval art. Mediæval architecture demands, however, for its elucidation that certain styles which preceded it and from which it drew its first inspiration should also be duly illustrated, such as the Byzantine and the Italian Romanesque, each including the branches by which it was led through other countries, and especially through Germany and France, with the changes it underwent by the way. The influence of Byzantine art upon the architecture of France in the twelfth century was direct. The foliage and the figure-carving, so well known in the earliest French Pointed-works of the latter half of that century, are for the most part directly derived from Byzantine carving and drawing, with a certain degree of influence from Italy, which was herself drawing freely upon Byzantine art. It is clear, therefore, that to illustrate Mediæval architecture properly we must possess ample specimens of these its parent styles.

The Vicars' Close, Wells.

The vicars choral formed part of the original establishment of Wells Cathedral, and were incorporated by Bishop Joceline in the beginning of the thirteenth century; and as he was a great builder it is probable that he built houses for them; but all that we have remaining of his time are some fragments of beautifully-sculptured ornament used up as old material, and built in the spandrels of the arches of the windows and in the parapet. These correspond exactly with his work in the cathedral, and with the remains of his palace at Wookey; but they may have been brought from some part of the cathedral now destroyed, and the original vicars' houses may have been of wood only, as was very usual at that period. These were rebuilt by Bishop Ralph, of Shrewsbury, in the fourteenth century; and he expressly mentions in his will the houses that he has built for the vicars, but all that remains of his work is the hall, with its west window and side windows. The east end over the gateway was lengthened in the time of Henry VIII. by Richard Pomeroy. The present houses were entirely built or rebuilt by the executors of Bishop Beckington, late in the fifteenth century, on one uniform plan, and several of these remain nearly perfect, though in many cases they have been altered, and two houses thrown into one. Nor can we complain much of this when we remember that the houses were originally intended for bachelors only, and each consisted of two rooms with closets at the back, but no offices. The vicars dined together in their common hall, and required no kitchen in their houses. The Close was, in fact, a college, in which each student had a small house, instead of his two rooms in a large one. The very beautiful gatehouse and bridge over the road from the vicars' hall to the cathedral is part of the numerous works of Bishop Beckington, one of the greatest benefactors of the city.

Paper Hangings.

These works may in some respects be divided into two classes—paper hangings proper and pictorial decoration. As regards the first of these the general principles are simple and obvious; large surfaces should always be quiet and unobtrusive in order to maintain that breadth and repose which is requisite, and should only be much enriched at the borders and edges, as, for instance, in the mouldings of the cornice or dado, or, as was formerly the case, and is now again practised, by means of those borderings which are manufactured for the purpose. The patterns of paper hangings, therefore, should be subdued and proportioned to the size of rooms; the colour should be rather inclined to negative than positive, to tints or shades rather than to full hues, and should be so equally distributed as to avoid violent contrasts, which rule will apply to the forms also; these should be treated flat and not in imitative relief. These rules are necessary to be observed to render the walls a background and subordinate them to the objects in the room, whether it be the furniture, the art or the occupants themselves. In addition to this, there requires such a variety both for colour and pattern as will admit of a suitable choice for aspect or for situation, so as to carry out or be in harmony with the other furniture. These conditions observed, the ornament may consist either of abstract forms or of floral adaptations. With regard to the second division, pictorial decoration, the more works are exclusively of this character, the more complicated and pictorial they are, the more unsuited they become for reproduction by machinery, and often the more distasteful when so produced. Too common at the best to be looked on with pleasure as works of art, they are impertinent and obtrusive in use, only fit for salons, cafés and such places where the meretricious supersedes the beautiful. It is desirable that these works should be separated by a wide interval from the former, and that great care be taken that the pictorial principle of the one does not interfere with or supersede the strictly ornamental principle of the other, since they have or should have nothing in common.

Copyright in Engravings.

In 1819 Mr. J. O. Robinson purchased the stock of the late Messrs. Boydell, and, in connection with Mr. Hurst, carried on the business of print-sellers and publishers. In May 1822 they entered into a written agreement to pay Sir Thomas Lawrence 3,000*l.* per annum for the exclusive privilege of having plates engraved from his pictures. Among the projects of Messrs. Hurst & Robinson were the portrait of the Duke of York and the two children (called "Nature"), engraved by G. T. Doo; the "Little Red-Ridinghood," engraved by Lane; and the portrait of George IV., engraved by Finden. For the privilege of engraving these, and two or three other subjects which were never finished, all from the pencil of Sir Thomas Lawrence, Messrs. Hurst & Robinson paid that distinguished artist 10,000*l.* Wilkie received 1,200 guineas for the picture of "The Chelsea Pensioners," painted for the Duke of Wellington; and 1,200*l.* from Messrs. Moon, Boys & Graves (who, after the failure of Messrs. Hurst & Robinson in 1825-26, purchased their stock), for the privilege of having the print engraved from it.

THE GORDON HOTEL.
BOSCOMBE.

Messrs Dancaaster & Taylor.
Architects.

ILLUSTRATIONS.

THE RETURN FROM CALVARY.

THE study we publish is one which the artist, the late JEAN PORTAELS, director of the Royal Academy of Painting, Brussels, considered to be among his happiest inspirations. The moment selected was supposed to be one immediately after the Crucifixion, when the crowd began to move towards Jerusalem. The subject allowed the painter to display the types of men and women he liked to paint, and the costumes which he most admired. Whether they were true to time and place is another question.

VILLA RESIDENCE, STOURBRIDGE.

THE GORDON HOTEL AND VILLA RESIDENCES ON THE STOURWOOD BUILDING ESTATE, BOSCOMBE, BOURNEMOUTH.

THE Gordon Hotel, now in course of erection on the Stourwood Estate, stands about 100 yards from the edge of the cliffs, and has uninterrupted views of Bournemouth Bay, Swanage, the Isle of Wight, &c. The site is about two miles from the centre of Bournemouth, and is beautifully surrounded by trees and shrubs of various kinds and growth. The Stourwood Estate, like the Bournemouth Public Gardens, is profusely studded with rhododendrons, and the roads on the estate are 50 feet in width, with pathways 10 feet wide, on which many trees are left standing and rustic seats interspersed.

The villa residences are among the first to be erected on this property, which was opened as a building estate at the latter part of last autumn, and which is now recognised as being the most charming and picturesque that has ever been introduced on the south coast. The villas each stand in their own grounds, and contain three reception-rooms, from seven to nine bedrooms and the usual offices, &c. The principal rooms in each house have a direct southerly aspect.

The hotel will be opened for visitors early in July next, and from the unequalled position in which it stands, will doubtless soon require extension. At present, however, there are but twenty-one bedrooms, and the public and private sitting-rooms range the whole of the south front and overlook the sea. There is also a spacious and well-appointed billiard-room to the hotel, extensive tennis-lawn, &c, and stabling in the rear of the grounds.

The whole of the buildings have been designed by Messrs. DANCASTER & TAYLOR, architects, Boscombe, who are surveyors to the estate, and in addition to their superintendence, the buildings will be under the supervision of the Christchurch sanitary authority, by whom all plans, sewers, and method of drainage have been approved.

CANTERBURY CATHEDRAL.

THE Dean and Chapter of Canterbury Cathedral and the representatives of the consistory of the French Protestant church in the crypt have at length come to an understanding as to the removal of the French church into the Black Prince's chantry. A considerable minority of the consistory, eight out of eighteen, are, however, strongly opposed to the removal. The floor of the Black Prince's chantry lies on a level some inches lower than that of the French church, to which at present it stands in the position of a vestry and vestibule combined. The minority urge that, in consequence of this, the chantry is always flooded in time of heavy rain. They also fear that if they submit to be ousted from that portion of the crypt to which they are entitled under a charter of Edward VI., it may be only a question of time before they are expelled from the cathedral altogether. The Bishop of Dover is, it is said, in favour of this course. However that may be, there is among the minority of the consistory an extremely bitter feeling against the Dean and Chapter, more particularly against those of the canons who are believed to hold more or less extreme Anglican views. At one time the Wallons occupied nearly the whole of the crypt. They used the greatest part of the large westward portion for their schools, for meetings and for practice in singing, but the assertion that they worked at their looms in the crypt appears to be incorrect. The feelings of the present

minority are thus naturally embittered by the recollection of their predecessors' prosperity. The removal to the Black Prince's chantry may now be considered inevitable, but before it takes place the chantry ought to be properly secured against floods, and the coats of whitewash and dirt which now conceal the colouring of the vaulted roof should be removed. When the portion of the crypt now occupied by the French church was restored as a memorial to Archbishop Tait, the beautiful Norman pillars and arches were painted all over with meaningless patterns in primary colours. The Black Prince's chantry should be protected against the risk of similar vandalism in future.

DURHAM CATHEDRAL.

IN a letter to the *Times* Mr. C. Hodgson Fowler writes:—

The interest taken in the recent discoveries in Durham Cathedral makes it desirable that some fuller account of them should be given, and with your permission I will do so, especially as in the report published in your columns of the 1st inst. there are several inaccuracies.

The excavations were begun with a view of ascertaining the nature and depth of the foundations of the present building and of the ground between them, and were purposely commenced at the junction of the Norman aisles with the Early English work of the nine altars; and the foundation-wall of the southern apse was then uncovered.

The existence of such termination to the aisles had always been a doubtful question, though Dr. Raine in his "Saint Cuthbert," written in 1827, gives a sketch plan showing them, but nowhere, as far as I know, gives any authority for them.

But he mentions that in the previous year the foundation masonry of the central apse was ascertained to be in a perfect state.

Of this apse we have now laid bare more than half the inside plinth, with one of the projecting blocks for carrying the vaulting shafts, and one base of a wall arcade precisely similar to the arcades in the choir aisles.

The exterior of the apse wall has been completely cut away by the Early English arcade round the feretory, but the existing remains show clearly that the apse was not surrounded by an ambulatory, but followed the plan of many familiar apses in Normandy.

But the foundations discovered of the two side apses present much greater difficulties as to their original date and design. They are both of roughly-hewn masonry (the ashlar mentioned in your account being Early English work built partly on the southern apse) and go down to the rock, which is 11 feet below the present floor-line—not more than 20 feet, as stated.

They are both about 9 feet 9 inches in diameter, and extend about 9 feet eastwards from the present inside termination of the Norman aisles.

The southern one is exactly central with the aisle, and at first sight seems as if it must have been part of it, but the centre of the northern one is some 6 inches north of the centre of that aisle, and therefore could not work in correctly with it. Eastward of each we have found a foundation wall running north and south at a distance of about 13 feet from the inner face of the apse.

Now as the walls of the choir are about 7 feet thick, and those of the aisles 5 feet 6 inches, it seems unreasonable to suppose that the eastern walls of the apses were made more than double the width of their side ones, and therefore these transverse walls must be taken as being of a different date.

Then the Norman walls of the aisles and of the triforium above are carried on in straight lines 14 feet to the east of the apses, showing clearly that Carilef's work did not terminate with them, as has been surmised.

But if his aisle walls were returned north and south on the line of the above-mentioned transverse foundations, they would give a square-ended chapel at the east of each aisle, with probably a low tower over each, judging from various indications in the upper part of his walling.

This would give an east end to the cathedral of great dignity, a bold semicircular central apse projecting from the east gable of the choir and flanked by two towers.

The question of the side apses still remains unsolved, and I venture to suggest that, as was at first thought, they are part of the foundations of Aldhun's church, probably of two apsidal chapels opening out of transepts. This would suppose a cruciform church with a somewhat short eastern arm, but which would be long enough to enclose the shrine of St. Cuthbert, placed where his grave now is.

And this theory would account for the removal of his body from Aldhun's church to the temporary "Tomb of stone in the Cloyster garth," which would have been unnecessary had not Carilef's church been designed to stand on the exact spot so long hallowed by the body of the saint.

ANTONIO CANALETTO.

WE noticed lately M. Moureau's "Antonio Canal dit le Canaletto," which forms one of the series of "Artistes Célèbres," published at the Librairie de l'Art, Paris, and printed some of the illustrations. We are now enabled to add a couple

Canareggio with the Canal Grande, is an eighteenth-century building and was designed by Carlo Corcellini. More interesting in the eyes of Canaletto was the Palazzo Labia, containing frescoes by Tiepolo, who used sometimes, it is said, to paint the figures in Canaletto's views of Venice.

The other view is reduced from one of Canaletto's etchings.

THE CHURCH OF SAN GEREMIA AND ROYAL CANAL, VENICE.

which show the difference between an engraver's works and an artist's etching.

The view of the church of St. Geremia is after one of Visentini's engravings, and, like his work in general, it manifests a desire to be faithful to the paintings. There is not much chiaroscuro, but if effects of the kind obscured the architectural lines they are better away. The weakest part is the sky. The church of St. Geremia, which stands near the junction of the

It is not exactly in the style with which his name is associated, for it cannot be called an architectural scene, but the buildings that were before him, although of little importance, were rendered faithfully. The plate explains the secret of Canaletto's success; he never sacrificed reality for the sake of picturesqueness. In other etchings he allowed himself a more dashing manner, and they are as free and unlaboured as could be desired, but the view given is more characteristic of his best manner.

SOCIETY OF ARCHITECTS.

SOME seventy gentlemen, mostly members of the Society of Architects, dined together last Tuesday night at St. James's Hall, Piccadilly. The chair was occupied by Mr. E. J. Hamilton, the president.

The loyal toasts having been given from the chair and

to be built, there were many to be restored, and perhaps he might be allowed to add that there were some to be re-restored, and we should all deeply regret if the material wants and resources should cripple the efforts of those who, up to the present time, had done so much.

Archdeacon Farrar, in replying, said the greatest triumphs of architecture had been wrought in the service of God, and

VIEW NEAR VENICE. (From an Engraving by Canaletto.)

heartily acknowledged, Mr. G. Candy, Q.C., gave "The Houses of Parliament," which was replied to by Mr. Atherley-Jones, M.P., who said it had fallen to his lot to promote a Bill in Parliament for the compulsory registration of architects, and that measure had that night received its first reading, and he hoped that he and those who had backed the Bill would be able to get it further considered in the present session.

"The Clergy of all Denominations" was given by Sir F. Jeune, who said there were many churches in this country still

throughout its entire history architecture had been the hand-maid of religion.

"The London County Council" was given by Professor Banister Fletcher.

Mr. Bassett Hopkins, who replied, defended the policy of the Progressive party.

Mr. Wyke Bayliss proposed "The Society of Architects and Architecture," which was acknowledged by the President, and other toasts followed.

DRAWING FOR PROCESS REPRODUCTION.*

THE title of this paper irresistibly reminds me of the knight's song in "Alice in Wonderland," which, as no doubt you remember, was called "Haddock's Eyes;" but that was only "what the name was called;" its real title was "A-sitting on a gate." In the song itself there is nothing whatever about gates or even about sitting. Now the name of this paper may be called "Drawing for Process Reproduction," but what its title should really be is quite another matter; perhaps later on a more reasonable description may suggest itself.

One of the most painful moments in the life of an expert is surely when he is introduced to a stranger, who immediately proceeds to instruct him in the mysteries of his own craft. It is like being retold a good story by the man to whom you told it. Politeness demands silence and apparent attention, but after a time the restraint becomes intolerable. As the elementary details are being more or less inaccurately told you, or the story is deprived of its point, you feel that the strained situation might supply a question of manners for a competition in a society paper.

Starting with idea of bringing together practical hints in the preparation of drawings for process reproduction, I soon saw that to do so would put me in the position of the superfluously garrulous outsider, if I attempted to expound first principles to masters of both crafts—that of drawing for reproduction and the reproduction of drawings, which are implied by the title of the subject for this evening.

The records of the Society of Arts are full of most instructive papers on Illustration in all its bearings. In the past Mr. Comyns Carr, Mr. Carmichael Thomas, Mr. W. J. Linton and Mr. Walter Crane, to name a few, all admirably equipped for their efforts, have delivered most excellent lectures. Only lately we had the pleasure of hearing Mr. Horace Townsend discourse on a branch of this subject, and still later, Mr. Henry Blackburn in a series of Cantor lectures covered the whole ground, or as much of it as any man could hope to do in a given time. Therefore, feeling it would be folly to attempt to traverse the field so thoroughly worked, all I can hope to do is to suggest a few side issues, which may provoke controversy far more valuable than anything I can say.

For, new though the art of reproduction by process is, it is already diverging into a hundred channels, and has its dogmas and its schools—as diametrically opposed to each other upon vital questions as could be found in any subject an Englishman deems worthy his attention. Not merely do artists differ on results, they are by no means agreed on methods—not only do craftsmen squabble over details, they fail to unite on matters of the first importance.

Roughly speaking, those interested in "process-work" may be divided into two camps—those who believe that nothing can be produced to-day better than the work of past centuries, and holding the ideal of the past to be unassailable, regard any attempt to modify it as flat blasphemy; and the other school, who, believing that altered conditions imply amended ideals, would fain open their eyes to all the defects of modern methods, not to condemn them merely, but to discover, if possible, ways to improve and perfect them.

It would be hard to think of any artistic topic with ideals more widely separated than, say, the Kelmscott Press edition of Chaucer, with its hand-made paper—archaic ornamentation and antique type symmetrically disposed on its pages—on the one hand and the latest French or American *édition de luxe*, with its shiny paper, its fine woodcuts, or half-tone blocks and its erratically arranged page, with illustrations splashed here and there, straying into the margin and at times in pale shades, wandering underneath the type itself.

One is forced to own that the conditions of modern printing—especially those that concern the periodical press—forbid a return to what we may conveniently call the Kelmscott manner. We may prize it as the perfect representation of an ideal that was achieved when printing was a fine art, and regret that for the future it takes its place with the arts that appeal to the classes rather than to the masses. For the attempt, excellent as it is, seems foredoomed to follow a not dissimilar effort to revive Gothic architecture in our daily life. We all know how, a generation ago, the casement and the sash window, the pointed arch and the square lintel, the interior of unadorned brick, with open timbered roof, and the plastered walls and ceiling, fought for the mastery. The rows of so-called Gothic villas in our older suburbs cease to charm us to-day, their spikey fascinations tempt in vain. The ugliest Georgian house satisfies us more because we see how an arbitrary attempt to adapt the externals of the surroundings to a past style was beginning at the wrong end, and that, after all, the art which accords most easily with the conditions of daily life and the needs of the average citizen is more likely to enshrine whatever art may be floating in the air at any period, than a deliberate

attempt to be artistic in uncomfortable or archæological ways.

The conditions of our time, requiring as they do rapid production and large numbers of impressions, with lavish illustrations, not merely of artistic but everyday subjects may be deplored, but it is wiser to recognise their supremacy. It does not seem disloyal to the ideal which ruled in the fifteenth and sixteenth centuries to accept machine-printing and process-blocks any more than it is acting disrespectfully to Westminster Abbey to live in a house with gas, electric bells and as much common comfort as the jerry-builder will give us.

Instead of trying to raise illustration by retracing our steps, and trying to be imitative fifteenth century—endeavouring to make a system which sufficed for a simple civilisation work under quite new conditions—would it not be better logic to accept machine printing, shiny paper, the process engraver and his works, and by mastering these new conditions—as the artist most assuredly can master any conditions if he set his mind to the effort—to create new ideals and set up new standards of taste and beauty? Possibly to do so must be to give up certain forms of expression very dear to many of us. We are the most sentimental nation under heaven. We prize ancient faults far more than modern virtues. But there is something the reverse of despicable in fighting with circumstances. To create a new ideal of a perfect book, with its pages illustrated by modern methods, printed by steam-power and produced at moderate prices; to leave such a standard that future ages, removed from the strife of tongues to-day, should deem characteristic of the twentieth century, and beautiful because it fulfilled harmoniously the conditions which called it into existence, seems worth trying for—worth many failures by the way.

For can anyone declare that the art of illustration, or, indeed, any art was the secret of any one age? What we do see is that the innovator banned by some of his contemporaries, who clung to past tradition, has often survived when the orthodox imitators of earlier ideals have ceased to be reckoned of any account.

To-day we are in the full swing of process reproduction, so much so that wood-engraving seemed but lately to be dying out, except perhaps in America, and in a few instances where artists such as Timothy Cole, Ellbridge, Kingsley, Charles Shannon, Charles Ricketts and a few others engraved their own blocks. Yet the last few months have witnessed a notable effort to bring it back to popularity in France and England; with that, however, we are not concerned to-night, but with the reproductive photographic methods for typographic printing. Of the various processes employed in book and periodical illustration to-day, there are, roughly speaking, two classes which are in general use—line work, for direct reproduction, and "half-tone," for the reproduction of wash drawings. The first, spoken well of by all men; the latter, a by-word, a thing for every critic to jeer at.

Taking the simpler process first, "to draw in solid black lines upon smooth white paper" is still the popular advice of the process man to the artist. His aim is naturally to get a drawing that will reproduce easily, and yield a faithful result without undue pains. Add to this a protest against too great reduction, a caution against employing parallel lines too close together, or isolated fine lines which will inevitably thicken, and, above all, a warning never to use grey lines—such as an exhausted pen is apt to yield, with many varieties of ink—and one feels the whole of the popular teaching on the subject is included. On the other hand, the pen draughtsman, eager to obtain more subtle effects, is inclined to rebel against these restrictions, to demand the freedom of using grey lines, and to mix up pencil touches with ink, if he be so inclined. Indeed, some artists seem to feel their one aim is to set the engraver a problem full of difficulty, and bid him improve on the effects they desire. Looking askance at both artist and engraver, the publisher is apt to draw a hard and fast line of so much "per inch," and to grumble at any overcharge; so the triangular duel between these conflicting interests is fought daily in many offices.

It is hardly necessary to go into these three sides of the subject here; indeed only an expert quite sure of his own position could exploit any one aspect of it adequately. Yet, leaving the debateable land where commerce and art are always struggling, one may claim that a new technique for pen-drawing has grown up of late years, which has so far had scant justice done to it by many critics whose ignorance of process is no excuse for the very unfair criticisms they offer. A pen-drawing may be excellent from the process man's point of view, and may so far imitate the style hitherto in vogue for woodcut to satisfy the older school of critics, and yet miss all the newer effects which are the joy of many students of the art. It is easy to dismiss the modern school as the work of a few geniuses who, by incessant practice, have become proficient—although it is a curious charge to urge to the discredit of a man that he is a genius who has taken infinite pains. Yet because it would be obviously foolish to advise any young artist to imitate the

* A paper read by Mr. Gleeson White on February 5 at the Society of Arts, in the Applied Art Section.

mannerisms of the style of any artist, we hardly solve the question by advising him to go back to the days of no style in particular, or by bidding him be content to imitate wood-engraving rather than to rely upon pure pen-drawing effects.

In drawing for process it seems necessary to warn beginners to shut their ears to most excellent advice of most worthy people of past days who were talking of quite another subject. Nor must reference to the splendid school of wood-engraving, which both the foes and friends of modern pen-drawing agree to praise, be held to constitute the final court of appeal. The drawings we think so admirable did not escape abuse from contemporary critics. Take the following passage, for instance, without its context, and it sounds like one of the furious onslaughts on our younger artists we meet not infrequently to-day :—

"The cheap popular art cannot draw for you beauty, sense or honesty, but every species of distorted folly and vice—the idiot, the blackguard, the coxcomb, the paltry fool, the degraded woman—are pictured for your honourable pleasure in every page, with clumsy caricature, struggling to render its dullness tolerable by insisting on defect—if, perchance, a penny or two may be coined out of the cockney's itch for loathsomeness. . . . These . . . are favourably representative of the entire art industry of the modern press—industry enslaved to the ghastly service of catching the last gleams in the glued eyes of the daily more bestial English mob, railroad born and bred, which drags itself about the black world it has withered under its breath. In the miserable competitive labour of finding new stimulus for the appetite—daily more gross—of this tyrannous mob, we may count as lost beyond any hope the artists who are dull, docile, or distressed enough to submit to its demands."

This diatribe, which had for its text the current number of the *Cornhill Magazine*, where Mr. Ruskin was writing, covers several pages of his "Ariadne Florentina," wherein he goes on to the conclusion that, "for total result of English engraving industry during the last hundred and fifty years, he was unable to get a single piece of true, select and comprehensive art to place for instruction in any children's school."

If, in 1876, the great art critic thought thus of the English school of wood-engraving we now appraise so highly, what matter if lesser men to-day regard the modern art of pen-drawing and process reproduction with somewhat similar contempt?

But this is only by way of warning to those who say that any cut-and-dried style of pen-drawing or woodcut has finally perfected a type for all successors. The man who has within him the instinct for drawing in black and white will ultimately find his own style, whether he employ the black blot of Vierge, the broken brush line of Japanese art, the finely-modelled lines of Marc Antonio, the attempt to work in pure line of one school, or an effort to give masses and values made up by lines unmeaning in themselves which distinguishes another.

If this most important question of style be too great to discuss, on the other hand it is not necessary to-night to go into details of the best ink, the most suitable papers, nor even to consider the important question of reduction—these things are excellently set out in many useful text-books. One man wields a brush with greater facility, another prizes a reed pen, another a Gillott, another a glass stylus—all these tools have their champions. But no one ever yet found the implement that insured a good result; that secret lies at the other end of the pen, in the hand and brain of the artist. It would seem obviously to the artist's interest to set down lines that experience tells him will yield the result he wishes. If, for special reasons, he wishes to obtain unusual effects, it is hardly fair to complain that the engraver is to blame should he not succeed at the first attempt to secure them. Some firms, as we know, take a pride in overcoming difficulties—which pride often flaunts its unwelcome presence in their invoices—others, bent on keeping down expenses, do the best within limits, and blame the artist for the failure. The game of setting problems for engravers, amusing to a cynic, is hardly so full of fun to the editor or publisher, who is not inclined to accord to all his contributors the attribute of genius, which rightly insists on making its own rules.

In face of all attack, one may venture to stand up for the popular illustrator, believing that, reviled by many, in high places of criticism to-day, his best examples will survive to attract the praise of connoisseurs of the future.

It was Mr. Pennell, I think, who said that "artists who show their work to the people through the press are doing as did the masters of other days, who spoke to the people through the Church;" and it seems no unduly sanguine prophecy to believe that of the best art we can produce to-day, a large proportion will be found in the popular publications of the hour. The same qualities that are needed for a good etching, which wears the purple of a recognised nobility, are required for what is even now considered its plebeian descendant, a good pen-drawing; but whereas in the etching the fat-inked line of the printer will give you even more than you expected, and, if you

are so minded, *retroussage* and other tricks may eke out the effects of your drawing, here we may be fairly sure that the first block, printed by the best process, will rarely, if ever, surpass the original. The actual relief of the ink on the drawing, slight though it be, is a very important factor, and this is not apparent on the smooth surface of modern books.

One could wish that for the sake of satisfying the eye, a method the reverse of hot-pressing could be adopted to destroy the shiny smoothness of the printed sheet to-day. Especially is this objectionable when the ink used has a lustre of its own, a metallic purple sheen which seems inseparable from some of the best half-tone printing. But although the decorative school can enjoy the luxury of hand-made paper, the artist of actuality the illustrator as distinct from the designer, may count himself lucky to get fairly good printing, even when he has accepted the inevitable smooth paper and the ink which produces the best results.

We all agree to consider the *Century Magazine* a typical example of excellent modern printing. In a conversation with Mr. De Vinne, he attributed its success, in great measure, to the American method of printing with a hard bed, so that the impact was almost a percussion rather than an impression.

Slow as English printers are to move out of their groove, there can be little doubt that both process blocks or fine woodcuts demand this style of printing, and that ultimately it will come to stay. Consequently, those who would control the coming fashion will hardly do so by holding aloof and resting content on the laurels of their old superiority in the days before process. If so, their power may slip into other hands, until we find the purely commercial ideal influencing the whole method. Therefore, it seems wise to warn artists against this certain change at no distant date, and to prepare them to face the American ideals, and do their best to remove its ultra-pretty features by working its methods on broader and more really artistic lines.

But although drawing by pen and ink is the chief method for the direct process, there are others which in capable hands can be trusted to secure most excellent results. Of course the clay boards, the mechanically tinted papers and similar devices can be most disastrously employed; but artists have before now—notably in the *Courier Français*, the *Chat Noir* and other French papers—not merely escaped disaster, but used these prepared boards or even the added tint—Day's shading medium—which was an offence to a recent speaker on this topic here, with admirable results.

A very safe way to insure accurate reproduction of a chalk drawing is afforded by using lithographic chalk on a sharp grain paper, not necessarily of extremely coarse texture. The oily nature of the chalk seems to prevent those lighter touches which yield greys in the original, and in the block either disappear or come out solid blacks—in either place to the detriment of the work.

With this facsimile chalk-work great reduction is undesirable, as the dots (shown by a powerful magnifying glass), clear and distinct, which build up equally the lightest and the darkest tints, cannot be reduced without great change—they vanish or else run together in masses, either result confusing the intended effect.

Fine lines are hardly possible in this work, unless it is treated on a larger scale; but beyond giving a mixed result not always pleasing, there is no mechanical objection to added touches by pen or brush that will supply those sharper accentuations of forms which are very hard to secure when working with the comparatively blunt point of this lithographic chalk upon rough paper.

To give an artificial grain to a smooth paper, some draughtsmen have worked with chalk upon a thin, hard paper (not unlike that used by typewriters), laid over a very rough piece of "Whatman" or the cloth cover of a book. You all know how easily a pencil-rubbing of the pattern upon a cloth binding may be taken; in this case the grain of the cloth is relied upon to break up the lines. The advantage consists in the fact that when the finished drawing is pasted upon a smooth board the surface offered to the camera is smooth. Only those who have had much practical experience of drawings and blocks can realise what an enormous difference this apparently secondary factor has in the result. The ordinary shiny and unattractive silver-print photograph and a platinum-type or bromide, which people, who know no better, call an art photograph, give quite different results, greatly in favour of the silver print. The same principle obtains with the smooth paper.

Another form of direct work may be produced from drawings made literally upon the photograph itself, upon a special print made upon salted paper. When the drawing is blocked in, the photograph is blacked and finishing touches are added. For work involving much fine detail—especially with complicated perspective—of such subjects as interiors of florid buildings, or a group of houses seen in acute perspective, this method offers a legitimate aid to the illustrator, especially if he be working against time.

Other tricks, such as "splatter" work and the like, need not be mentioned. Of these it all depends who uses them. Nothing is heterodox to an artist; he makes the meanest things obey his purpose. Everything, however, justified by precedent, is capable of being used offensively in non-artistic hands.

It would serve no purpose here to go into technical details, to consider, for instance, to what extent cross-hatching is desirable. Personally, it seems to me, if used to imitate the method so frequent in debased wood-engraving, it is undesirable. Indeed, for the freer art of pen-drawing for process, to bind itself within the limitations of the older methods is obviously absurd.

With regard to "half-tone," we find "process" in its weakest and also in its most popular form. It is unquestionably beloved by the people to-day, and also barely tolerated by artists. Indeed, half-tone is the favourite object for attack by nearly all the exponents of the higher criticism, and it is a tempting subject for ridicule. The "moral pocket-handkerchief," as it has been called, with its flat, grey surface, its ugly, mechanical network, and its fatal facility for multiplying the cheap photograph from life—small wonder that it has become the scapegoat of photography against whom every man's hand is raised. When one studies the blocks that illustrate the dozens of Academy guides and special supplements, especially those printed in pale shades of violet, green and magenta, one feels the only advice to offer to those about to draw for half-tone reproduction is the classic "Don't."

Yet here and there we find blocks quite as good as those produced by the imitative school of wood-cutting that preceded them, which were employed freely in America, and jealously admired here but a few years ago. As the half-tone engraver to-day is equal to anything you can offer him, one need not say much of the preparation of drawings for this class of block, beyond a warning that as the white network has a trick of lightening the darks, and lowering the lights of the original—that it is wise to draw in a more violent key, with exaggerated contrasts of lights and darks. It is advisable also, now that the camera registers too faithfully any alteration of colour, that the same pigment be employed throughout the drawing, whether it be in oils or water-colours; otherwise, if black and dark brown are used together with dead white and blueish white, the block resulting will record these shades which the artist only intended to appear as different "values," not as different colours.

But the half-tone block at its best may be left to confound all its detractors. On the walls here is a reproduction of a photograph of a carved wooden altar-piece, by the Swan Engraving Company, which not merely surpasses any woodcut, but beats the most perfect platinotype photograph for strength and delicacy combined.

The tone-block as it leaves the process-worker's hands seems to have reached its limit, and for advance we must look for artistic development in the added work of the graver. Now, handwork upon the block until quite recently has merely added fresh horrors; the cut-out backgrounds white, with the figures in harsh, untidy silhouettes against them, the coarse white scratches and the patchy effect of the engraved work upon the etched has been preposterously absurd. Here is an amusing example of the touched-up block and the untouched.

The remedy appears to be in the artist's hands; he must learn to use the graver, himself working on his block, as some artists—Mr. Harry Furniss for one, I believe—do to-day. Then he might reasonably prepare his work accordingly, and leave certain details for after touching up. For instance, the hair of figures might be left in a mass of black, or certain shadows put in with solid washes, the white lines to be added afterwards. It is quite easy, I believe, at a particular stage of half-tone to burnish down the white network in given parts, and to leave in their place solid blacks.

Judiciously employed, these masses often give vigour to a block, and whether prepared with a view to lightening by hand-work or deliberately planned as solid masses to stay, there can be no doubt as to their value in certain cases.

The mania for great reduction is possibly nearly exhausted, and one can only hope it will never revive. A specious prettiness and preciousness it had, but the temptation it offered to slovenly drawing and its forlorn dependence on the printer to redeem the result from being a mere muddled smudge, would alone suffice to condemn the practice. When a drawing the size of half a page of the *Times* was reduced to the dimensions of a postage stamp, the *reductio ad absurdum* was surely complete. Yet if report be true, many of the vignettes that illustrated the popular series wherein "Tartarin" and "Madame Chrysanthème" appeared were subject to some reduction. The dainty little woodcuts which seem to be in imitation, or at least in rivalry of process, by Florian and others, such as have been appearing in "Le Bambou," show a new departure probably destined to be highly popular. For myself I fail to see that they are a great advance on the best half-tone. They certainly appear to print better, and at first

there is a charm in finding the lines of the drawing full of interest in themselves, but after all they are the engraver's lines and not the artist's. True, in the best instances they may be even better than those the artist put down; but one may be sure that, once the game becomes widely played, the second-rate engraver, the mere mechanic, will cut away the refinement of the artist's drawing, as he chopped it out of existence in former days.

(To be concluded.)

THE ALABASTER INDUSTRY.

AN interesting report on the Volterra alabaster industry has been prepared for the Foreign Office by Vice-Consul Carmichael, from which we take the following:—

In 1893 only about 250 travellers—persons, that is to say, bent on seeing the sites and antiquities of the place—visited Volterra, sixty-nine of whom were English or American, forty-four Germans, thirty-nine French or Swiss, and the remainder Italian. And yet Volterra is a city that every English school-boy—thanks to Lord Macaulay—has heard of, nor would any history of the world be complete without some account of the part she has played.

The city of Volterra is of immense antiquity and its origin is lost in obscurity. But it can with some show of probability be demonstrated that it was in existence nearly 4,000 years ago, and it would seem safe to accord its alabaster industry an almost similar antiquity. Volterra was one of the twelve cities of the Etruscan League. In its Etruscan days the population of the city must have been quite 100,000, and the huge cyclopean walls which surrounded it had a circumference of 7,965 yards. Portions of these walls which still survive are of a height of 40 feet and a thickness of 13 feet. The southerly side of the town forms a line with the site of the ancient walls, and it thus happens that one of the original Etruscan gates which is standing, the famous "Porta all' Arco," forms also one of the entrances to the modern city. The local museum ("Museo Guarnacci"), a model of good order and perspicuous arrangement, contains nearly 600 Etruscan cinerary urns of curious and beautiful workmanship. Fully two-thirds of them are made of alabaster, and are thus a convincing witness to the time-honoured antiquity of the alabaster industry. Indeed, the whole city is still redolent of Etruscan traditions and Etruscan influences, and it would be impossible rightly to comprehend the modern industry without to some extent bearing in mind its venerable origin.

The country round about Volterra is bleak and desolate, but has a certain savage grandeur that is not unimpressive. Low bare hills and hillocks of clay, deeply fissured by the strong rains and with few perceptible traces of culture, lie around for a considerable distance. It has been well described by a picturesque and observant writer as "a region which . . . looks as if the waters of the flood had here subsided in violent agitation, the hand of man never having touched it since; hills of clay, whitened and cracked in the wind, without a sign of verdure or blade of grass, save here and there a twig, parched to the colour of dry mud, of which it was an abortion." It is in the midst of such country as this that the Volterra alabaster abounds.

Speaking generally, alabaster is to be found nowhere in the world outside the province of Pisa. Sweeping as this statement may seem, it will yet stand the test of examination provided there be no verbal misunderstandings. Oriental alabaster, the alabaster of the Bible, which is chiefly found in Egypt, is not what is nowadays ordinarily understood by alabaster, but is really a species of marble; it is a carbonate of lime, whereas the alabaster of Volterra is a hydrated sulphate of lime, a distinction sufficiently emphatic to mark the sharp difference between the two. Then the alabaster found at St. Jean de Maurienne, in Savoy, is alabaster only by courtesy, for it is said to be of so poor a quality as to be only fit for conversion into plaster-of-Paris. The so-called Derbyshire alabaster is of much superior quality to the French, and it is even worked into ornaments and used in altar decorations, but it would seem to be so far inferior to the alabaster of Volterra as not to merit classification in the same category. Other sources of alabaster or alabaster-like substances might be indicated—Rellsthal in Tyrol and Bormio in Lombardy, for instance; but here again the poor quality of the mineral or the insignificance of the quantity leaves Volterra without any appreciable rival. The alabaster of common parlance is, then, solely and exclusively the alabaster of the district of Volterra and other outlying districts, all within the province of Pisa. Stress is laid upon this fact because it is important, as it is also interesting, to show that the rough material of an industry of world-wide celebrity and world-wide diffusion is really confined within a very limited corner of one particular country of the globe.

There are many different kinds of alabaster found in the

whole district—Dr. Targioni Tozzetti, writing one hundred years ago, has elaborately described fifty-two varieties—but it will be sufficient for all practical purposes to divide the whole class into five clearly defined species.

1. The white alabaster of Castellina, a luminous and transparent stone of faintly cerulean tint.

2. The white alabaster of Volterra, a mineral of an opaque milk and even creamy white colour.

3. Veined, striped or spotted alabaster in its many fanciful and beautiful varieties ("Alabastro macchiato").

4. Bardiglio, a greyish stone of the nature of alabaster, which, when cut and polished, has something the appearance of the grey marble known as "Dove" in the English trade. This is the cheapest of the alabasters.

5. Agatised alabaster, called at Volterra agata, an extremely beautiful yellow stone varying in colour, when polished, from dark amber to deep rich brown. This is much the rarest and most expensive species of alabaster.

The Castellina alabaster is especially prized because of the large size of the blocks which are found. Nearly three-fifths of the alabaster for sculpture which is excavated at Pomaia is in blocks weighing at least over 6 cwt., while blocks of from 17 cwt. to 20 cwt. are of common occurrence. Indeed, Signor Ottaviano Ciampolini has this year sent to the Antwerp exhibition a block weighing 58 cwt., and having a length of 5½ feet. Such a find, however, is phenomenal.

The worked alabaster industry is divided into two strongly differentiated branches, firstly, sculpture, *i.e.* sculptured representations, whether on a large or a small scale, of the human form; secondly, the miscellaneous industry, *i.e.* the countless other objects manufactured at Volterra, such as vases, ewers, pillars and stands, baskets, clock-cases, frames, toilet necessities, animals, fruits, ash-trays, candelabra, crucifixes, holy-water stoups, &c. (Signor Pietro Volterrani's catalogue enumerates eighty-five different kinds of articles which may be purchased in his establishment.)

These two divisions of the worked industry correspond also with the two main divisions of the rough material, and coincide with the two territorial divisions that we have mapped out, for the alabaster used in what is called sculpture (alabastro da scultura) comes exclusively from the Castellina district, while the alabaster used in the miscellaneous industry (alabastro da industria) comes chiefly from the second and larger district. There is yet another point of division; nearly all the best sculpture of alabaster is now carried on in Florence, whereas the miscellaneous industry is almost wholly confined to Volterra city.

Walking along the by-streets of Volterra the ear is arrested by the clinking of little hammers or the grating rasp of files, and looking in at a doorway the passer-by will see two or three men busily engaged, with all the absorption of true artists, in fashioning the various parts of a vase or a flower-basket. These men may be a father and two sons, or an uncle and two nephews, or three men united in an informal partnership, or (very rarely) one man employing two others, and they usually unite in themselves the qualifications required in the production of a vase, one being a turner (tornitore) who gives it shape, the other a modeller (squadratore) who fashions its pillar and base, the third a decorator (ornatista) who carves its decorative adjuncts of fruit and flowers. The master-worker with his busy band of workers and apprentices has disappeared, and it is from these small workshops that the articles of the miscellaneous alabaster industry now go forth to the world. The workers sell chiefly direct to the proprietors of the Volterra "gallerie." A proprietor will bring a block of alabaster and a block of agata to the workshop and say, "Make me a vase and a stand out of these;" or the worker will purchase the rough material himself, fashion different articles and carry them to the "gallerie" on the chance of a sale. Then there is the waif and stray of the trade, often a mere youth, who lives a very precarious existence, buying a small block of alabaster when he has a few "soldi" to spare, working it into various articles and selling them, when he can, to the "gallerie" or to the chance traveller (a rara avis, as has been shown), or carrying them even, when times are very bad, to the neighbouring farmhouses, where he is glad to exchange his works of art for bread and beans and a little thin red wine.

The great cheapness of objects in alabaster—possible only by the hardy frugality of the workers and the low cost of living at Volterra—has tended to cast an undeserved slur upon the industry. So cheap are the smaller articles, that many people are led to believe that they must be produced in some way by machinery. The humble vendor who boards a British ship in Leghorn harbour, to display his wares, is often met with sceptic incredulity when he explains that all the articles he has for sale are the product of patient hand-made labour. How could existence be supported if such were the case, is the very natural question which occurs to those who have had practical experience of such offers? The writer of this report was offered for 4 lire, at Volterra, a small vase, an ambitious combination of alabaster and agata, which he would have thought

cheap at 15 lire, and its needy-looking maker reduced his offer to 2½ lire in the hope of doing business.

There are about 550 workers of alabaster in Volterra city. (Baedeker's estimate—two-thirds of the population—is nowadays quite beside the mark. "Central Italy," 11th edition.) The wage they earn would seem to Englishmen, ignorant of Italian frugality and contentedness, hardly sufficient to keep body and soul together. It is difficult to estimate with any approach to accuracy the value and the quantity of the worked industry of any one year. About 4,000 cases of goods are said to leave the city annually. The average weight of each case is 1 cwt.; the average value from 70 to 100 lire. It would not be to overestimate to fix the annual value at 15,000*l.*, and this figure should, perhaps, even be increased when the value of the sculpture done at Volterra comes to be taken into consideration. There are about half a dozen establishments in Volterra which merit the name of "galleria," among the principal of which are those of Signori Pietro Volterrani, Pietro Trinciarelli, Niccolò Biagini and the Società degli Alabastri.

Agata is mainly used for making pillars or stands for vases. The rich tawny yellow of this stone contrasts finely with a white or delicately-veined alabaster vase, the *tout ensemble* producing a most pleasing and artistic effect. It is also used, with an unfortunately misguided taste, as a decorative adjunct to small white vases and frames. The neck and handles of a vase, for instance, will be of agata, while the body is of alabaster, the result being, it is to be feared, essentially vulgar. Bardiglio shows to best effect in large vases of a free bold design, and it is not unpleasing in animals of fair size, as, for instance, a pair of lions or horses.

An artificial polish is given to all the articles of the miscellaneous industry. The object is first thoroughly rubbed and cleansed with shagreen and horse-tail ("equisetum sylvaticum"), and the final polish is given by the application with a woollen cloth of a paste compounded of bone-dust and common soap.

The sculpture of alabaster used at one time to be carried on principally at Volterra, but about twenty years ago this branch of the industry migrated to Florence, where it took root very firmly, and speedily assumed considerable proportions. Twenty years ago the caves of Signor Ferruccio Ciampolini used to furnish only 1,000 kilos. a year to Florence; they now send over 1,000 kilos. a day, a fact which sufficiently accentuates the revolution that has taken place in this branch of the industry.

There are six or seven important galleries in Florence, the principal of which are those of Signori Frilli, Lapini, Bazzanti, Vichi and Romanelli. All do a large export business chiefly with America and Germany, the Americans taking most of the modern sculpture, the Germans the copies from Classic models. Unlike the alabaster articles of Volterra, the sculpture is not subjected to a polish, but to a whitening process which is as follows:—The figure is immersed in water which is gradually raised to boiling-point, and then allowed to become quite cold again before it is taken out. Great care has to be exercised, as too much heat would reduce the alabaster to plaster, and a too sudden exposure to the air would cause it to crack. This process deadens the too great transparency of the alabaster, and gives it the appearance of fine white marble. The alabaster of Castellina is alone susceptible of this treatment; if tried upon white Volterra alabaster the result would be to give it the semblance of a plaster cast. Let it again be noted that Castellina alabaster, and Castellina alone, is used in this industry. It is now very generally coming to be called Castellina marble (marmo di Castellina), owing, no doubt, to the unreasonable prejudice against the idea of alabaster that exists among many people.

About 500 workers, including the sculptors themselves, are engaged in the Florence industry. Proprietors of the gallerie in giving a commission for the execution of a work used to provide the rough material. They now expect it to be found by the sculptors and workers themselves, who thus incur an additional responsibility. There are two depositories of the rough material in Florence belonging severally to the Brothers Ciampolini. From having to deal with six or seven large customers (the gallerie) they have now to deal with some hundreds of small ones, and their business has become in consequence much more elaborate and not a little irksome. A word of praise must be accorded to the good order and attractive arrangement of the gallerie. Each bust or figure stands upon a pedestal of pietra verde, bardiglio or agata with revolving top, and can thus be thoroughly and comfortably inspected. The establishments are of imposing dimensions. The value of the worked industry of Florence in the course of a year cannot be less than 20,000*l.*

Volterra, Florence, Leghorn and Pisa are the only cities of Italy where alabaster is worked. The industry at Leghorn has greatly declined owing in some measure to her disadvantageous position on the railway. Few chance travellers come to Leghorn, and the chance traveller is a very important factor

in the alabaster industry. But we still have the considerable studio and galleria of Signor Cesiano Vannetti, which is entirely devoted to the production of sculpture. Some twenty-five men are at present employed here and in a busy season the number of workers has been as many as fifty. The same style of work is done as at Florence. The copies from the antique are particularly good and fully equal to those of Florence. Modern sculpture is also done by Florentines specially transplanted for the purpose. The Leghorn sculpture being less famous than that of Florence is consequently cheaper, and the fact that it is made in the port of shipment gives it special advantages and facilities as regards export. The total value of the industry in a good year amounts to quite 2,000*l*. The galleria of Sigg. R. Bartoli & Co. in this city is also worthy of note for its excellent selection of objects of the Volterra miscellaneous industry.

A great quantity of articles in alabaster is sold at Pisa, and no inconsiderable quantity is worked there. Though Pisa has altogether lost her old favour as a winter residence for strangers, the number of hurried sightseers who stop to see the famous group of the Duomo, the Leaning Tower, the Campo Santo and Baptistery is enormous, and many of them are ready purchasers in the tempting alabaster shops with which the city abounds. Volterra, Florence and even Leghorn furnish Pisa with her stocks, but she also does some of her own work. The value of the worked alabaster—chiefly sculpture—produced in Pisa in one year amounts to about 4,000*l*., while the value of the articles sold there annually must be fully double that amount.

Among the several causes that militate against a greater prosperity in the alabaster trade in general, the most prominent to the impartial observer will seem the unsuitable taste that prevails both in the sculpture of Florence and the miscellaneous worked industry of Volterra. In the former branch, classicism, late and early, Greek, Roman and Canovan runs riot, together with products of an utterly opposite pole, a flashy, vulgar modernity and would-be realism, which gives us roguish dancing girls, coquettish diving girls, faultlessly clad pifferari, impossibly spruce *lazzaroni*, improbably prepossessing *monelli* and a host of other creations, half realistic, half romantic, which however possible in pictorial art cause something like a shudder when contemplated in cold alabaster. The great revival of Christian and Gothic art which has taken place in this century and that now so largely influences the taste of the educated classes of all countries, does not exist for the sculptors of Florence or the workers of Volterra. The churches of Italy teem with the most beautiful objects, but of all the famous pulpits, fonts, statues and images they contain, scarcely an example is to be found in the alabaster galleries, though the pliant graceful material would lend itself admirably to the reproduction of such models. An impression must exist that people would not care for them. How mistaken this impression is a small fact will help to show. At Pisa alabaster models of the celebrated Duomo and Baptistery and Leaning Tower are freely made, and they sell largely. Without question a fresh impetus would be given to the alabaster trade if a fresh current of taste were introduced into the worked industry, and the Italian sculptors and workers need go no further for their new models than to the rich treasures of Italy's churches and palaces.

In the miscellaneous worked industry of Volterra, the prevailing taste is little less deplorable. The elaborate florid design of the vases is such as our grandmothers in the thirties and forties were wont to delight in, but of the severer, simpler taste that now happily finds much favour, Volterra is all unconscious. Another regrettable fact is a certain perversion of taste in the selection of the objects worked up. A picture-frame, for instance, however beautiful the workmanship, becomes an incongruous and uncomfortable object when worked in alabaster. The same may be said of the countless little canons with guns of agata and carriages of alabaster which are made at Volterra. And surely the alabaster representations in unblushingly realistic colours of fruit and flowers and birds are artistically extremely reprehensible and cannot but tend to lower an industry which has a very reasonable claim to be considered one of the fine arts. But the climax of incongruity is, perhaps, reached when we are asked to admire an alabaster model of a modern twin-screw fast cruiser, fully rigged and mounted, and equipped with all the panoply of war.

Still while making these few strictures on the faults in taste which are exhibited, faults which certainly do not arise from any innate bad taste on the part of the workers, but from a belief that they please, it is impossible sufficiently to admire the exquisite skill which is manifested even in the meanest objects. The secret of swift, sure, deft-handedness has, more or less unconsciously, been passed on from father to son, and the workers are justly proud of the venerable antiquity of the art and its mellow traditions. Volterra need fear no rival in her special branch of the industry, for she is secure in customs and traditions that cannot well be copied, and this branch of the art at least would surely perish in any forcible attempt at transplantation.

THE ARCHITECTURAL ASSOCIATION.

A LARGE party of members of the Architectural Association visited last Saturday the Pavilion Theatre, White-chapel, which we fully illustrated in our last issue. Mr. Ernest Rüntz, the architect, under whom the recent remodelling of the theatre has been carried out, met the party and first gave them a short address describing the alterations which he had made in the old theatre and the reasons which had led him to make the various improvements, especially the consideration of the class of patrons of the theatre, which, as Mr. Rüntz well pointed out, is of vital importance in the designing of any theatre. The Pavilion Theatre for comfort, safety and enjoyment now is an excellent model of what a people's theatre should be. White-chapel and the great East End of London is not only the home of poverty, but a vast number of the middle class who make the backbone of the population, and the Pavilion provides for the middle class an entertainment and a place of amusement equal, except only in cost, to any they can get in the West. After listening to the architect's address and inspecting the plans, the members were conducted by Mr. Rüntz, his assistants Mr. Belcher and Mr. Ford, and Mr. Cohen, the manager, over the various parts of the theatre, and as rehearsal and scene-painting were going on, they learnt as much as one afternoon could teach of the making of a theatre. Refreshments provided by the architect were then enjoyed, and the proceedings ended by a vote of thanks to Mr. Rüntz, proposed by Mr. B. F. Fletcher, the hon. sec. of the Association in charge of the visit.

English Archaeological Study in Greece.

SIR,—In the notice of Professor Durm's proposed restoration of the Lion of Chaeroneia in your issue of the 15th, you stigmatise the work done by English students in Greece as merely "a little pottering which may help to entertain a few ladies and officials." It is true that the British School of Archaeology in Athens, with an income from voluntary subscriptions of barely as many hundreds as the French and German Governments spend thousands on their respective institutes there, cannot acquire a first-rate library or undertake feats of archaeological engineering like the excavations of Olympia and Delphi, or maintain a staff of specialist professors such as are attached to the other schools. But it does not need a very minute study of the reports of the Antiquaries, the Hellenic or the Royal Geographical Societies, to show that a sound training is being provided, and solid work is being produced by our own institution; and the names of Messrs. Penrose and Gardner, its past and present directors, and of Messrs. Hogarth, Munro, James, Loring, Bather, Woodhouse, Stuart-Jones, taken at random from the roll of students, are commonly associated by archaeologists with something more than "a little pottering."—I enclose my card, and remain, yours, &c., ONE OF THE POTTERERS.

Oxford: February 19, 1895.

GENERAL.

Mr. Alfred Gilbert, R.A., has been elected a member of the Athenæum Club by the committee, under the authority of the special rule.

Herr Winter, of the Berlin Museum, has discovered that the marble figure described as "A Greek King as Hercules," is a portrait of Mithridates Eupator.

The Council of the Royal Society of Painter-Etchers on Tuesday elected the following Associates of the Society, viz. W. S. Hale, J. C. Murray.

The Aberdeen Harbour Commissioners have resolved to proceed with a scheme of harbour improvements, which is estimated to cost about 46,000*l*.

Miss May Morris will lecture on "Mediaeval Embroidery" in the Applied Art Section at the Society of Arts on Tuesday, the 26th inst.

The Institution of Civil Engineers meet on Tuesday, the 26th inst. Among the papers on the programme is one by Mr. Robert Robertson, on "Electrical Haulage at Earnock Colliery."

Lincoln's Inn Fields, which will be opened as a public recreation ground on Saturday, has cost the County Council altogether 13,000*l*.

Mr. W. B. Richmond, A.R.A., will begin a course of lectures on the "Evolution of Sculpture" to the students of the Royal Academy on Thursday.

The Architect.

THE WEEK.

MR. EWAN CHRISTIAN has departed from us after a life which was almost enviable. He had passed his eightieth year; he had acquired the respect of the numerous architects who met him as the representative of the Ecclesiastical Commissioners. It might be said that the greater part of his life was spent in the exercise of judicial functions, and he fulfilled his duty with a sense of justice which was never surpassed in any of the courts of law. As he once said of himself, "Mine has been a life of independent service, not of exploits. I have undoubtedly done much work, and some, I hope, of a valuable kind to those most interested; but I could not think of comparing myself with the great architects and archæologists of our own and other countries. My highest ambition has been that of doing to the best of my ability the duty from time to time set before me to accomplish, and of maintaining unsullied in every sense the high character of an honourable and independent architect." These manly and yet modest words expressed an ideal of character which nobody could dare to say was not in keeping with Mr. CHRISTIAN's daily life. He held an onerous office, and he never endeavoured to turn its functions into indirect advantage for himself, as has happened in other times and places. Sometimes he found his duties trying, as when novices, immature or unskilful architects, endeavoured to uphold their notions against his experience, but in the end he generally enjoyed the satisfaction of a rational victory. Mr. CHRISTIAN, in fact, made the duties of his office more onerous to himself by the pains he bestowed in trying to raise the character of many of the designs submitted to him, and, if it were not for his endeavours, we are afraid a great many churches would have a more unpleasing appearance. His own work, whatever the style, was always in excellent taste, but he could not escape the fate of all critics in the arts. He became over fastidious, and designed as if his powers were restrained. It was as a judge that his keenness, honesty and skill were most apparent. Mr. CHRISTIAN's report on the designs for the Edinburgh Cathedral is a model of its kind. Every line reveals the knowledge of a master who was competent to recommend alterations in the work of the ablest among his contemporaries, and who was not afraid to express his own preference. Many architects have had reason to be grateful to Mr. CHRISTIAN, and we trust the respect for his memory will be expressed in a permanent form.

By the death of THOMAS EDWARD BRIDGEN Manchester has lost another experienced architect. He was born at Wolverhampton in 1832, and served his articles with GEORGE COTTINGHAM, whose Mediæval proclivities are remembered. Mr. BRIDGEN commenced business in Manchester in 1859, in partnership with Mr. PENNINGTON. One of the earliest important buildings designed by Mr. BRIDGEN, and erected under his supervision, was the Hospital for Sick Children at Pendlebury. This was the first hospital built in this country on the pavilion system, and it has served as a model for many others. On all questions relating to the designing, planning and fitting up of hospitals he was an authority. Although at one time very warmly in favour of the pavilion system in preference to any other, in later years experience led Mr. BRIDGEN to modify his views so far as to consider a corridor hospital under certain conditions but slightly inferior. The remodelling of the sanitary and other portions of the Manchester Royal Infirmary was entrusted to him. The enlargement of Stockport Infirmary, Ancoats Hospital, and other institutions were also carried out under Mr. BRIDGEN's advice. In London his firm has constructed at Winchmore, for the Metropolitan Asylums Board, a hospital comprising accommodation for 850 patients. Amongst other buildings Mr. BRIDGEN designed and erected in the Manchester district were St. Bride's Church, Brooks's Bar; St. Clement's Church, Chorlton-cum-Hardy; the spire of the church of Holy Innocents, Fallowfield; the Inland Revenue offices in Mount Street; a block of offices at the

corner of Albert Square and Cross Street; the Eye Hospital, Oxford Street, besides numerous warehouses and private residences. He designed and erected a block of buildings for the Queen's Building Society in John Dalton Street and Deansgate, Manchester. The designing of this building gave Mr. BRIDGEN great pleasure, as it was surrounded by four streets, and, having somewhat a free hand in thus making a completed block, he produced what is perhaps his happiest work—a specimen of English Tudor suitable to a large town. In 1894 the partnership with Mr. PENNINGTON was dissolved. Mr. BRIDGEN was subsequently engaged up to the time of his death as joint architect, with Mr. CHARLES HEATHCOTE, in the collaboration of designs for the further enlargement of the Manchester Royal Infirmary. Mr. BRIDGEN gained the reputation of a firm friend, a cheery companion and an able architect.

THE London County Council have inflicted more injury on the ratepayers through the medium of their Works Department than is ever likely to be realised. On Tuesday a sort of atonement was offered for past misdeeds by passing a resolution which would be an obstacle to similar extravagance by their successors. It was resolved:—"That the works committee should keep separate accounts in such a manner as to show the cost of each work executed; that the actual cost and final estimate should, as far as practicable, be ascertained and certified within three months after the completion of the work; and also that half-yearly statements should be prepared showing the amount of the original estimate and the amount of the certified actual cost." There is characteristic presumption in this endeavour to compel a new Council to adopt a different sort of book-keeping. If a system of the kind is useful, why was it not employed from the first attempt to meddle with contracting? It is to be hoped the new Council will be able to make use of the methods which are familiar to men of business, and, unless we are mistaken, it will need only a short experience in Spring Gardens before the conclusion is arrived at that the Works Department must be transformed. Although it is in a scandalous condition, we doubt if it is the worst—that is, the most extravagant—of the Council's creations.

THE unsatisfactory arrangements in connection with the Chicago exhibition have caused much loss to exhibitors, which is aggravated by the indifference of the American people to a state of affairs which should be considered as a national disgrace. A case arising out of the exhibition, which came before the Queen's Bench Division in Dublin on Monday, suggests how wide are the effects of American mismanagement. The plaintiffs brought an action to recover a sum of 36*l.* balance of account for freight for the carriage of a number of stone crosses, the property of the defendant, who is the proprietor of the Ardbraccan quarries, and also for taking care of the crosses until the close of the exhibition on October 31, 1893. The defendant counter-claimed against the plaintiffs for negligence on the part of the plaintiffs' representative at Chicago for not properly taking care of his exhibits, with the result that the crosses were taken possession of by the exhibition authorities after the close of the exhibition. The plaintiffs' case was that their duties with reference to the defendant's exhibits ceased at the close of the exhibition in October, and that they were not responsible for anything that had occurred to them after the 31st of that month. At the trial the jury found for the plaintiffs for the full amount of their claim, and on the counter-claim they found for the defendant 15*l.* damages for negligence on the part of the plaintiffs prior to the close of the exhibition, and 150*l.* damages for negligence subsequently. The plaintiffs then moved to set aside the verdict for the defendant for 150*l.*, on the ground that there was no evidence of any contract by which any duty was cast upon them to take care of defendant's exhibits after the close of the exhibition. The Court unanimously set aside the verdict obtained by the defendant on the counter-claim for 150*l.* The result is according to law, but is it not discreditable to find the authorities of the Chicago exhibition seizing on a number of Celtic crosses which a too confident Irishman entrusted to them?

HUBERT ROBERT.*

SO many speculations have been offered about "the harbingers preceding still the Fates and prologue to the omen coming on" of the French Revolution, we have often wondered why the paintings of HUBERT ROBERT were not utilised for that purpose. If Destiny wished to create riddles as forewarnings to the French nobles, what could better serve the purpose than the countless pictures of the ruins of Roman greatness which he painted? France was in a moribund condition in the middle of the eighteenth century; but, as usually happens with such patients, was indifferent about the consequences. The works of HUBERT ROBERT would have served as texts for any philosophers who cared to predict future events. But nobody was disposed towards that sort of exercise, and the painter least of all. Although he might be supposed to have spent his hours of relaxation in reflections among the tombs, there never was a more joyous man. Life had few sorrows for him. When he had fallen on the gloomiest days, and was awaiting for months in the prisons of Ste. Pélagie and St. Lazare to be ordered off to the guillotine, his liveliness could not be overcome. Death seemed to be kindly disposed towards the old *gamin de Paris*. After his liberation he fared better than the majority of artists who had served royalist patrons, and when the inevitable hour at last arrived the artist was in his merriest mood, awaiting his wife in order to accompany her to a dinner-party. As his admirer Mme. LEBRUN, the painter, said, the happiness which accompanied him through life was not absent from his death. If HUBERT ROBERT had been destined to produce symbols of warning, he performed his task without much suffering to himself. DIDEROT, who generally tried to make the best of things, could not understand why HUBERT ROBERT did not introduce melancholy and meditative figures amidst his Classic ruins. If the painter had been more of a philosopher he would probably, by figures and other means, have endeavoured to express the pathos of neglected and debased examples of architecture. ROBERT, however, accepted decay as inevitable, and he was glad that time had graciously permitted fragments to survive which were adapted as subjects for his paintings and drawings. He belonged to an age when artificial ruins were considered to be the fitting accompaniments of gardens and pleasure-grounds.

There never was a painter, and we are not forgetful of CANALETTO and PANINI, who was more reverential towards architecture than HUBERT ROBERT. To display his reverence he jeopardised his life. Born in 1733, he was brought up for the priesthood, but the Latin classics, which had almost become a native language for him, only made him imagine the greatness of Roman buildings. To realise his visions he ignored all the parental plans for his future and ran away from the ecclesiastical college to Rome. His one ambition was to represent Roman architecture. If HUBERT ROBERT had known more of ordinary life he would have tried in Paris to earn a studentship in the French Academy in Rome. But he was only a neophyte who had been brought up secluded from the world, and he imagined it was only necessary to offer himself to art as other candidates presented themselves to the monks and he was sure to be received with welcome. Fate was kinder to him than to the majority of those who seek after greatness along irregular paths. At the time the Marquis de MARIGNY, a brother of the POMPADOUR, was in power. He was destined to be one of the rulers of France, and it was considered requisite as such to make of him an authority on all that relates to taste. He was, therefore, sent off under the tutelage of COCHIN and FRAGONARD, to Italy, in order to inhale, as it were, all the mysteries of æsthetics. Through the influence of the Marquis young ROBERT was allowed to share in the advantages of the education of the Villa Médicis on bearing a part of his expenses. The artist remained eleven years in Italy and during that period there were few of the more noteworthy ancient buildings which he did not represent.

When he returned to Paris he was in difficulties for a time. HUBERT ROBERT'S training was irregular. He

was, to a great extent, self-taught, and at the time that method was not appreciated. In the middle of the eighteenth century monopoly prevailed in art as in other kinds of business. The little that the Académie Royale let pass was seized by the Guild of St. Luke. The only opportunity for exhibiting allowed to artists like HUBERT ROBERT, who did not bear the official stamp, was on an occasion when there was a religious procession. Some of the public places were then hung with tapestry, and for the few hours the drapery remained pictures might be attached to the pieces. Many painters, who afterwards became famous were first made known to connoisseurs in that way, and HUBERT ROBERT was probably compelled to adopt it. But he was not long destined to follow an irregular course. In 1766 he presented himself as a painter of architecture, with examples of his paintings, before the Academy, and without further delays he was admitted. The election was a testimony to his abilities and to the influence of Mme. DE POMPADOUR and her brother. In the next Salon, among the numerous pictures he exhibited was one, *Ruins of a Triumphant Arch and other Monuments*, which was described as being prepared for Bellevue, the château that was erected by Mme. DE POMPADOUR. That entry in the catalogue was enough to make ROBERT'S fortune.

The list of the works he produced until the close of the century is amazing, not only from the number of pictures, but the adherence to one class of subject. In London a painter in oils who produced a representation of a building could not expect to find a purchaser. The reason is that among us architecture is not esteemed by the public. On an average HUBERT ROBERT exhibited a dozen paintings of architectural subjects in every Salon. They were derived from Rome and its neighbourhood, Frascati, Tivoli, Naples, Florence. Occasionally we find a representation of a more distant work, as *Ruins of the Famous Portico of the Temple of Baalbec at Heliopolis*, or *Marius seated amidst the Ruins of Carthage*, or the *Ruins of a Temple Built in Athens*, but they were derived from sketches by some other artist. St. Peter's in Rome was made the subject of several paintings. Architecture was not treated in the eighteenth century with the exactness which photography has made necessary. ROBERT, like PANINI, was regardless of actuality, and brought buildings together in his pictures which were separated, if by doing so he thought he could produce a more effective composition. One of his pictures was *A Greek Temple with the Colonnade of St. Peter's*. Another was *A Ruined Palace, under the Arcade of which is seen the Cupola of St. Peter's*. Besides hybrids of that sort, we find combinations such as *The most Celebrated Antique Monuments of France*. One of the pictures reproduced represents the Porte Saint-Denis, the Fontaine des Innocents, the church of Sainte-Geneviève, the colonnade of the Louvre, and the astrological column of CATHERINE DE MÉDICIS, forming one group. This painting must have been a late work, for in the centre is the Lion of St. Mark, from Venice, which was among the revolutionary spoils. There were occasionally views in Paris. One represented the removal of the centres of the arches of the Pont de Neuilly. As was to be expected, not one of HUBERT ROBERT'S works depicts a Mediæval building, although France possessed an abundance of picturesque examples. His reputation as a man of taste would suffer if he placed Notre-Dame or St. Etienne du Mont on canvas.

The criticism on his works revealed more appreciation of the qualities that were necessary in a painting of a building than would be found in our time. The effects of light and shade on grand masses, the perspective and the detail are noted. "All ROBERT'S pictures," wrote one critic, "are imposing; by the magnificence of the edifices he has selected for subjects he seems to surpass his models and to be more *recherché*, more finished, more French." His *Grande Galerie* was admired for "the immense depth that is rendered with a light touch, the play of light on numerous objects, and the seductive harmony of tones." DIDEROT'S notices are especially interesting. About one, where the arrangement of the picture was symmetrical, he said:—"There is probably more poetry, more of the accidental in a cabin, but certainly in a tree that has endured years and seasons, than in the whole of the façade of a palace. We must ruin a palace in order to make it an object of interest.

* *Les Artistes Célèbres; Hubert Robert et son Temps.* Par C. Gabillot. (Paris; Librairie de l'Art.)

In fact, there can be no true beauty without the ideal. The beauty of the ideal strikes all men; the connoisseurs alone are arrested by execution." At another time we find DIDEROT objecting to the appearance of ROBERT's sketches in the Salon:—"If this artist will take to sketching he will lose the habit of finishing; head and hands will become libertines. If he sketches now when he is young, what is he to do when he grows old? He wishes to gain ten louis in a morning, because as he is extravagant and his wife elegant money goes quickly. But talent also goes, and an artist who was born for greatness becomes mediocre. Acquire the habit of finishing, M. ROBERT, and in time you will find it will be as easy to produce a picture as a sketch."

HUBERT ROBERT's works were able to sustain criticism. Examples were considered necessary for every gallery which aimed at perfection. His rivals in the same line were beaten out of the field by his vigour. ROBERT attained official rank, and he gained a tenement in the Louvre. It suggests the inevitable connection which was supposed to exist between ruins and gardening when we find him in request as a designer of picturesque grounds. The grand style of LE NÔTRE had fallen out of fashion. It is not improbable that HUBERT ROBERT, while living in Italy, had seen examples of the gardens which were laid out by the Scottish gardener, JACOB MOOR, who died in Rome in 1793. Under his direction the gardens of the Villa Borghese on the Pincian Hill were laid out, and he was the first to delight the Roman artists with an English garden. MOOR introduced sculpture and architecture as features, and his ideas and ROBERT's corresponded. One memorable work entrusted to the latter was the rearrangement of the rockwork and sculpture at Versailles, known as the Bains d'Apollon.

The prospects of HUBERT ROBERT at the beginning of the reign of LOUIS XVI. were hopeful. He was not only designer of the royal gardens and peintre du Roi, but in 1789 he was appointed as one of the two custodians of the king's pictures at the Louvre. In a little time there was a change. The Bastille fell "like the city of Jericho by sound" in July 1789, and immediately ROBERT produced for the Salon a painting of it during the first days of its demolition. He was also suspected of having made over some of the royal pictures to the district of St. Germain-l'Auxerrois adjoining the Louvre. The Salon exhibitions were held in 1791 and 1793 as if France was not in the throes of revolution. HUBERT ROBERT, as usual, exhibited pictures of ruins, tombs, and fragments of antiquity. The party known as the Mountain gained the upper hand in August 1793, and the Reign of Terror began. A few days after the execution of MARIE ANTOINETTE, HUBERT ROBERT was arrested as a suspect and lodged in Ste. Pélagie. It is generally understood that his denunciation was the act of DAVID, the painter. Both were admirers of ancient Rome, but there was no clashing between their works. One painted architecture, the other long-legged, excitable figures. ROBERT saw Roman buildings, but DAVID drew from imagination. If DAVID did not send ROBERT to prison, he made no effort to free him, and for a time his power was not limited. HUBERT ROBERT accepted his lot in a very quiet and manly way. He did not pose as a hero, like so many of the revolutionists. Among his companions in prison were AUDRAN, of the Gobelins, ROUCHER, the poet, MILLON, the archæologist, and RESTOUT, the painter. ROBERT was able to read and to paint. He sometimes utilised the plates on which his food was brought in instead of panels, and his sketches on them found purchasers, especially among English amateurs. Some of his companions were summoned before the Convention and duly passed under the hands of M. SAMSON and his assistants. For nearly a year ROBERT remained in prison, daily expecting sentence. The fall of ROBESPIERRE brought the Reign of Terror to an end, and on the 17th Thermidor of the year II an order was given to ROBERT's wife for his release.

He was hardly free when he was appointed by the Convention one of the five citizens who were placed in charge of the National Museum of Arts, which was afterwards known as the Musée Central des Arts. ROBERT and his associates had care of the works of art belonging to

the nation. In the course of a few years the collections were increased by the most valuable works in Europe. The Musée Central became the Musée Napoléon. A new organisation was created, and ROBERT and his associates retired on pensions. All parts of the Louvre were required for the new treasures. Accordingly, ROBERT and the artists who were privileged to have *appartements* were evicted. Fortunately, he possessed a house at Auteuil, and there he resided in comfortable circumstances until his death on April 15, 1808.

Architectural subjects have long ceased to attract, and in consequence the painters who gained a temporary reputation by them have been overcome by oblivion. Until M. GABILLOT undertook the duty, there was no biography of HUBERT ROBERT that possessed the least value. As substitutes were articles in encyclopædias, in which a few stereotyped statements were repeated without examination, M. GABILLOT has spared no exertion to discover the truth, and the literature of art is at last enriched with a biography of HUBERT ROBERT that is worthy of the subject. It contains also much information about the artist's contemporaries, and the volume is one of the most delightful of all those which relate to that fascinating but until lately most neglected epoch, the eighteenth century.

BIRMINGHAM SCHOOL OF ART.

THE annual distribution of prizes to the students of the Birmingham Municipal School of Art took place on Friday in the large theatre of the Birmingham and Midland Institute, by Mr. W. J. Wainwright, A.R.W.S.

Mr. Wainwright, according to the *Birmingham Post*, in his address to the students said the present distribution differed from those in preceding years inasmuch as the committee had invited for the first time an old student of the school to undertake the honour and responsibility of performing that ceremony. That was an act of recognition from the committee to the old students, and they saw in it an indication that they had given to the committee some cause for satisfaction, and that they had used not unfaithfully the advantages which the committee were able to give them in days gone by. He asked his old fellow-students and colleagues to call his voice their own, and said they would raise it first in affectionate tribute to those city fathers to whose unwearied zeal in the cause of art the community owed so much—to Alderman Kenrick, to Mr. Bunce, and their colleagues past and present. Those names which his audience had received so heartily would be held in honour so long as art should be esteemed and unselfish devotion to public duty accounted a virtue in their midst. To them the students owed the advantage of having had the early guidance of their revered master, Mr. Taylor. He had been to them a good master, for by example and precept had he shown them what it was to be an artist; and wherever their subsequent steps might have taken them, his early influence had not been effaced and could never be forgotten. Far back in the middle of the century a movement was set on foot to secure for the industrial arts of Birmingham the artistic training and education essential to their prosperity, and the School of Art was established and carried on its early work for years in comparative obscurity through the dark days of departmental experiments—for art demanded of her votaries, both Government departments and individuals, a long apprenticeship. Faithfully the Birmingham school had served her apprenticeship, and to-day they beheld her a municipal institution, a peerless school of art and an administrative achievement worthy of the best traditions of the city. The first students laboured in the dawning light, the present students stood in the noonday, and it was to impress upon the latter to value at their true worth the priceless advantages they enjoyed that he was there that evening. In athletics any appreciable lapse in his progressive training entailed the physical impossibility of the athlete reaching the highest excellence. So it was in art-training. There was a consistent change going on in the students themselves, not only physically with regard to hand and eye, but in the mental vision also. For instance, in many points of painting and criticism young painters were not always in sympathy with mature work, nor did the particularisation of young painters satisfy entirely those who had attained to broader visions. It followed that the mature work was satisfactory or the reverse, so far as finished artistic expression was concerned, exactly in the measure in which the artist had profited by the succeeding changes of his condition to acquire in those periods all the power of expression that it was possible for him to acquire. Experience had determined in art training the exercises most conducive to the gradual acquisition of that power of expression, and he wished to advise them, and especially the younger students, never to lose sight of this

condition, upon which their ultimate success was dependent, but to pursue their progressive studies with conscientious completeness, doggedly if the studies should be irksome, ever bearing in mind that neglect in this respect would most likely entail some regrettable deficiency later on. The mind of the designer must not only be exercised and trained, it must be nourished and supported. This food for the mind might be obtained from countless sources. One of the characteristics of a fertile mind was its capacity to draw sustenance from any and every source capable of yielding it, but the acknowledged and necessary sources were found in nature and the best examples of decorative and ornamental art. From the alembic of the mind this mental food came forth again in new proportions and character, and this coming forth was ordered by principles which were the foundation of style. Without style there was no ornamental art worthy of the name—it was an incoherent babble, out of joint and worthless. They saw that three principal factors went to the education of a designer; he must first acquire by training power to express ideas; he must then sustain those ideas by improving his mind; and, lastly, he must be taught style with which to order the expression of his ideas. All these three factors were independent, and should as far as possible be equally cultivated. It must be the artist's endeavour to echo the harmony of nature in every part of his work. He must not be satisfied to have beautiful ideas, he must not rest content in presenting those ideas conformably to the ordering of style, but must in every touch by which he gave expression to them preserve the utmost consistency and harmony. In many works dealing with the principles of art unfortunate allusion was made to the freedom from rules, principles and other constraints which genius was said to enjoy, and consequently the young student often committed the pardonable error of wondering if he was a genius, and, ending by giving himself the benefit of the doubt, failed to obtain useful knowledge and guidance. It was much better to assume that there was no such thing as genius in the art of design, and the artists whom he had known to possess most claim to the title had been precisely those who had most respect for principles and rules, and who, knowing most about them, were ever studying and drawing inspiration from the best examples of art. The student who, under the impression that he had originality, pursued a different course, would assuredly labour only to find out his inability to do anything of lasting value. Art, to truthfully reflect nature's harmony, must be continuous, and art could not be continuous unless she ever rested on and proceeded from what had gone before. Practice, no less than theory, insisted that all art development must have its roots in the past, and the stronger and deeper those roots were the nobler and stronger would be that development. The knowledge of historic art must not be limited to text-books, but must be obtained at first hand under proper direction, and the supply must be continuous. French artists, whether painters, designers or craftsmen, continued their academic studies long after they had achieved a reputation, and that, no doubt, was a principal reason why they were able to maintain their reputation. Cessation of study at any period of an artist's career was the herald of decay. To the industrial artist there was another powerful and ever-present reason for keeping himself within the influence of past ideals, and that was the inevitable and lowering effect of commerce upon art. It must not be thought that the association of commerce with art was a calamity, for, as they knew from history, commerce had over and over again protected and fostered art. When commerce from protecting art came to degrade it, they should first inquire whether artists had been true to themselves or their profession. It was necessary to remember that art and commerce were distinct in their nature, and although often in alliance could never be united. To make this clearer he would instance one engaged in the production of articles of commerce, and which at the same time professed to be objects of industrial art. Here, apparently, art and commerce were united, but they could only be united in a sense if the articles made were made in a commercial spirit; but that meant ruin to their art quality. Whilst the craftsman was at his work he must be an artist and not a commercial man, but in planning his ware to suit requirements in the disposal of it, and in all else than the art part of it, the commercial spirit might be exercised with advantage, but art must be kept intact. The commercial man was not to be held answerable for art, and when he passed the line of sound honest commercial principle and followed a policy which right-mindedness could not approve, he was then working direct or indirect injury to all worthy interests, commercial and artistic alike. When that line had not been passed art had benefited by contact with commerce. It was well, then, that artists and art craftsmen should approach the matter frankly and see how far they themselves had to answer charges of tradiness and bad taste. Let each examine for himself how far in his professional career he had made an effort to keep up and improve the tone of his work by continued study, and in how much he had allowed surmountable difficulties to obscure the bright aspirations of youth. When they looked round and noted the reverent care

with which the relics of the past were treasured, whether they were valuable or not, provided that they conveyed some message from the past, and the widespread disposition of the people to grace their daily life by beautifying their surroundings, they recognised that they lived in an appreciative age, and he would remind them that great opportunities which others had sighed for in long disappointment and neglect lay before them. They would encounter difficulties, and failure would often attend their best efforts, but they must bear it in strong patience, for success was reached through failure. Exacting or unsympathetic conditions of employment might tempt them to do less well than circumstances would admit of, but he advised them to meet that temptation with the knowledge that to yield to it was to risk loss of artistic character. That might sound to them like a counsel of perfection, but it was a condition of success. The cynicism with which ardent enthusiasm of beginners was so often chilled by those who had had experiences proceeded too frequently from the hopelessness resultant upon the conscious loss of tone confirmed by the gradually acquired habit of doing work, not as well as it could be done, but only sufficiently well to pass muster. He had said that commerce could not be saddled with the censorship of art, but commerce was constrained to accept what art offered, and if art was truly exercised, even at cutting prices, the public who again were dependent upon artists for their art would in the end learn to prefer good from bad art, and commerce even of a bad type would acquiesce. In a word, it was possible, if artists were true to themselves and their profession, to cause bad art to be unmarketable, and when that point was reached another golden age of art would begin. They were entering on their profession, and in process of time would represent the industrial art of the city, which would be what they made it. He hoped that their enlarged opportunities would enable them to make the art of their city better than they found it, that they would emulate the past glories of industrial art and seek to excel them, nor forget the spirit which animated the artists and craftsmen of old. Right in mind and strong of heart, their predecessors had shown that that pure exalted ideal in industrial art was no delusive mirage, that commerce was no canker. They had left us the secret of amassing wealth whilst elevating art, and though their wealth had perished, their art remained to show the high ordering of their daily life and thought. Humble in worship, proud in patriotism and thorough in everything, they had left us an example of what the artist citizen should be. It was for the students of Birmingham to study, treasure and follow that example in the interests of the art to which they were devoted and the city whose reputation it was their proud duty to uphold.

YORK ARCHITECTURAL SOCIETY.

At the ordinary meeting of the above Society, held at the Church Institute, Mr. A. Pollard, past president, in the chair, Mr. J. W. Longfield, of the Art Metal Works, Otley, read a paper on "Wrought-iron Work." The lecturer dealt very exhaustively with his subject, and in the course of his remarks said that no material was more worthy of study than wrought-iron, for no substance on earth had more profoundly influenced the destinies of the human race. Though it was the cheapest of metals, and lacked many of the intrinsic qualities of the precious metals, it immeasurably surpassed the whole of them together in interest and in its value and utility to us. As regards its principal attributes, it stood among the metals as the working masses stood in a civilised community, and had ever proved a most mighty instrument for good or ill. The discovery of immensely rich ores of iron in almost every part of the world, and of fuel fit to reduce them, had already inaugurated a period of decline in the production of iron ore in this country, and should lead us to prepare for the inevitable change from the raw produce mart to the art-produce mart of the world, which must ensue if we were to maintain our trading supremacy in the future. The recent movement in favour of the adoption of wrought-iron work for architectural and domestic purposes in preference to the hard geometric productions of the foundry had caused one to wonder why this beautiful art had become superseded by cast-iron. He was afraid that cheapness, as in a great many other things, was responsible for it. A peep inside our old cathedrals, such as York Minster, amply demonstrated the love of our forefathers for the beautiful examples of the smith's art which were now coming to the front again. If forges superintended by experienced smiths could be erected in our technical schools, he was sure that many young men would learn the craft, and not only improve their means, but produce a supply of mechanics which was really becoming needed. In accuracy and finish the English workman was all that could be desired, but when they looked for taste, idea or originality, he was most disappointing. Furthermore, it was often next to an impossibility for a smith

to execute the designs of many architects except at a great cost, whereas a similar effect might easily be obtained if the architect had a slight knowledge of the material in which the design had to be made. In conclusion, Mr. Longfield urged that if architects and those engaged in the building trades were to apply themselves more fully to the study of the craft, wrought-iron work as an art would make greater strides in the future than it had ever done in the past.

IDEALS OF PAINTING.

A LECTURE on the above subject was lately given by Professor Baldwin Brown in the Art Gallery, Glasgow. The branch of art to which he principally limited his remarks was decorative mural painting, a branch he chose because it had already been little treated of here and was a subject of great importance to an urban community. He pointed out that little had been done by painters of this country in the way of mural decoration, and consequently its methods were imperfectly known in Great Britain, but it was a department which ought to be encouraged in Glasgow, whose school had the good fortune to possess artists fitted to shine in that department. After indicating how the ideals of painting and the standard of excellence among early Italian artists differed from those of later painters of Spain, Flanders and Holland, and specially how vastly Rembrandt had widened the field of art, Professor Brown proceeded to dwell particularly on fresco work. He chose as his principal example the great decorative paintings of the roof and east wall of the Sistine Chapel, by Michel Angelo. After illustrating the manner in which that Titanic artist bent the architecture to his own purposes, Professor Brown showed in detail the various decorative subjects with which he filled the space at his disposal. The lecture was illustrated with a full series of lantern slides of the Sistine Chapel compositions, and in addition to these a number of the most famous pictures and of the fresco decorations of other public buildings were shown and commented on in a most graphic manner.

DECORATIVE DESIGN.

ON Friday Mr. Charles F. A. Voysey, architect, delivered a lecture in the Manchester City Art Gallery on the subject of decorative design. The meeting was arranged by the Manchester and Salford Association of Master Plasterers and Painters.

Mr. Voysey, in the course of his address, said once remove the strait-jacket of convention in decorative design, and place beauty of thought and feeling above beauty of expression, and the hands of men would soon find their cunning, and art would again be a living power among us. Perhaps when the public had given up telegraphing the rise and fall of railway shares there would be left a little more sympathy for the poetic and imaginative senses, and our playful delight in bird life and strong joyful colour would not meet with so much indifference and disdain. At present it was idle to look among the many for the appreciation of pleasures enjoyed only by the few. Too often the decorator became a sort of head foreman whose opinion was not always asked, and indeed was often scornfully rejected. He was expected to carry out the ideas of others, although he had probably spent his life in the study and practice of his craft. His client, often the lady of the house, did not consider this, but would rather turn, fresh from the mysteries of millinery and with a head full of notions begotten of Parisian fashion books, to her daughters for counsel and suggestion. The decorator, with his years of experience, had to stand patiently by and listen to verbose feminine dogmatism upon a matter to which in many cases his client brought neither knowledge nor aptitude. Think of the hardships the decorator had to endure who was at the mercy of the present generation of upholsterers and furniture makers. Did not the presence in nine thousand out of every ten thousand houses of bastard French, German, Italian and English furniture of the Renaissance persuasion foredoom the decorator's labours? Could it be possible to produce grace, dignity, repose or cheerfulness in the presence of such vulgar, ostentatious lumber? Truly, under modern conditions the decorator's life was a very hard one. It was partly brought on by himself, by his immoral readiness to supply anything, and in fact be pulled by the nose by the public for the sake of the pounds, shillings and pence got out of them. Events in history, political, religious and social bias all affected our taste to an extraordinary degree, but were in fact a most unsound foundation for it. If the painter needed freedom to express the best in him, why not the decorator? If the craft of the decorator was raised from the position of a commercial enterprise to that of an art, it would cease to be necessary for men to strain every nerve and fibre to advertise themselves. Sculptors, painters, decorators, designers and architects must join hands one with the other

over a common object, not to make money out of each other, but to further artistic knowledge and feeling. The lecturer gave some practical hints in illustration of his subject, and urged in conclusion that as a matter of education they ought constantly to strive for simplicity in all they did, and encourage it among their clients, and he was sure that if that was done there would grow up an appreciation of quality rather than quantity.

TESSERÆ.

Concrete Construction.

S MEATON having observed a portion of the outer wall of Corfe Castle in a remarkably leaning position, like the tower of Pisa, was induced to examine it, and found the interior filling of the walls to be of rough rubble and fragments from the quarries cemented with a mortar composed of lime, "doubtless originally of good quality," and a considerable admixture of sharp sand and pebbles, which had evidently been poured in in a fluid state. From what he saw here he adopted a similar method of building the rubble backing of the first lock on the river Calder. Rondelet states that the columns of the choir of the church of Vézelay, in Bourgogne, were ascertained to be of artificial stone by Marshal Vauban, and that the pillars of the church of St. Amand, in Flanders, were made in the same manner. He tells us also that at Lyons concrete is used for wharf walls and the piers of bridges, and that with the Metz lime concrete arches may be constructed without bricks or stones, and these arches will form a single piece as hard as stone. Bélidor states, indeed, that in Metz most of the cellars are so constructed; the gravel used is from the river; and he says that when set the concrete will resist steel-pointed tools. According to Sir William Reid, the walls of the fortress of Ciudad Rodrigo, in Spain, are of concrete, the marks of the boards, which retained the semi-fluid matter in their construction, being everywhere perfectly visible. Besides sand and gravel round boulder stones were employed. These were from 4 to 6 inches in diameter, procured from the ground around the city, which is everywhere covered with them. The Bridge of Lladonet, six leagues from Barcelona, consisting of two rows of arcades placed the one on the other, was entirely constructed of concrete. One of the lower arches gave way from the work being carried up too hastily, and the work was abandoned, but M. de Betancourt resumed it, and raised the bridge to a height of 150 feet, on a length of upwards of 700 feet, with perfect success. Treussart relates that the Italians at Alexandria make very good concrete blocks with the Casal lime, and employ them in angles. They are 4 feet 8 inches long, 2 feet 8 inches wide and 2 feet 8 inches high. They are buried underground for two or three years, and there attain great hardness. He says that Colonel Finot constructed at Strasburg an arch of concrete of 13 feet 4 inches span, which succeeded very well, and that a similar arch was constructed at Schelestadt.

Teutonic Yotens in England.

When our forefathers came into this island they found it covered with Roman towns and buildings, as well as with monuments of an earlier population, in the shape of cromlechs, vast entrenchments and other similar works. With the character and uses of the Roman buildings they were perfectly well acquainted, but they looked with greater reverence on cromlechs and barrows, and indeed on all earthworks of which the origin was not very apparent, because their own superstitions had taught them to attribute such structures to the primæval giants of their mythology, who were objects of dread even to the gods themselves. They believed that the spots on which they stood were under the immediate protection of beings of a higher order than humanity, who frequented them at the silent hour of night, and whose anger it was perilous to provoke. The Saxons brought with them a multitude of mythic traditions and stories relating to their gods and heroes, which they had preserved through ages of which we have no historical account, and the scene of which had been successively placed in every country where they had made a settlement. Many of their stories had thus become located in England when the introduction of Christianity worked a sudden change in people's belief, and what were merely mythic personages were looked upon either as the real heroes of former days or as so many devils and evil spirits. The mythic legends were still current as romances, and continued to exist under altered forms as romances of chivalry, and under various subsequent degradations, until they were at last hawked about the streets in the still humbler form of penny chap-books and nursery tales. It was in this manner and by such gradations that the mighty deeds of the god Thor against the giants of Jotenheim became transformed into the exploits of Jack the Giant-killer. But the peasantry were unacquainted with all these literary vicissitudes. With them the earlier legends were intimately connected with localities, and the names of Woden, and Thor, and Weland

and the rest were often preserved when they had been long forgotten in more cultivated society, and their stories were as often handed down traditionally with very little transformation. When John Leland made his antiquarian tours in the reign of Henry VIII., these local legends appear to have been extremely numerous, and he has alluded to several of a very interesting description. The topographical antiquaries of the seventeenth and eighteenth centuries also make frequent allusions to them, but unfortunately they looked upon them with contempt, and seldom condescend to do more than barely mention them. We may cite one example from the "Itinerary" of Leland, who (vol. v. p. 101), speaking of Corbridge in Northumberland, says, "By this broke, as among the ruines of the olde town, is a place caullid Colecester, wher hath beene a forteres or castelle. The peple there say that ther dwellid yn it one Yoton, whom they fable to have beene a gygant." The giant race of the Northern and Teutonic mythology were termed "Jotens" or "Yotens," in Anglo-Saxon "Eótenas." To them the early Anglo-Saxon poetry attributes works of immense power or antiquity—the mounds and earthworks of ancient days, as well as the weapons and other articles found within them. The wonderful sword which Beowulf found in the den of the Grendel's mother was thus a weapon of Eotonish make. In the same manner the antique vessels of gold found by Wiglaf in the cave in the mound of the dragon slain by Beowulf are described as "ancient work of the giants." At a later period Layamon, who breathes a pure Saxon spirit, describes the giants who (according to the fable) first inhabited Albion as being Eotens.

Latin Mosaics.

A variety of pictorial mosaic may be designated as Latin, since it long retained the marked peculiarities of style which distinguish Latin from Byzantine art. Thus, not in the choice of subjects only, but in the retention of the ruddy flesh-tints, the deep brown shadows and the stumpy figures and simple costumes of the decline of Roman painting do such mosaics as those of the fifth century at Santa Sabina, Santa Maria Maggiore and San Paolo Fuori delle Mura at Rome differ from later specimens executed in the same city, if not by Greeks alone, at least by a preponderance of Greeks over the direct descendants of the original classical mosaicists. Barbet de Jouy remarks that "the mosaics executed from the time of Constantine to the pontificate of Nicholas I. (A.D. 858) do not possess the Byzantine character." This, though partially correct, is far too sweeping an assertion; it suffices, however, to show that the separation in classification of Latin from Byzantine style in mosaics is essential to preserve a correct idea of real, not fanciful, distinctions. The earliest Christian Latin mosaic known is that which lines the vaulting of the little baptistery of Santa Costanza adjoining the basilica of St. Agnese, and dates from the age of Constantine. It would be extremely difficult to say which was the latest. The more closely the matter is studied the more evident it becomes that a distinct Latin influence in the history of art is to be traced running beside, mingling with, but never altogether losing its identity in the great tide of progress which swept from a thousand springs and sources over the whole continent of Mediæval Europe. Thus amongst existing remains of the Middle Ages we may point to three in particular in which many of the Latin peculiarities of mosaic working have been faithfully preserved to a comparatively late date, one in the North of Italy and the other two in that district over which we may frequently recognise traces of the influence exercised by the long-flourishing Latin schools of Aix-la-Chapelle and Cologne. In the pavement of the cathedral at Novara, a work executed at intervals probably between the beginning of the twelfth and the middle of the thirteenth centuries, we meet with a very fair reproduction of a black and white classical pavement. In various medallions are birds and allegorical figures. From this may be readily observed the coincidence which occurs between the tessellation of the Novara pavement and that of the ancient pavements of Pompeii. It is probable that a somewhat similar mosaic pavement, with figures representing Rhetoric, Logic, Prudence, &c., and a zodiac, was formerly in the church of St. Irene at Lyons, a city in the neighbourhood of which many fine classical mosaics existed which might have well served as models.

Restoration of Buildings.

In the hands of an experienced and painstaking restorer it often happens that a design which had been almost utterly lost is in a very great measure recovered, but this can only be done by long and patient study of the fragments discovered; and the work should be indefinitely postponed until these can be thoroughly explored and thoroughly studied. Too much stress cannot possibly be laid upon this. It is the very pith and marrow of restoration. If neglected it is destructive to the work, though if carried out fully it is the great redeeming fact which compensates for many of the annoyances which restoration involves. In such cases all the fragments which can be

by any means grafted into the restored work should be brought in at whatever cost. In difficult cases let the architect stick to it hard and fast until his difficulty is solved, and let him set by as lightly as possible the conjectural theories which, one by one, occur to him, for he may almost depend upon it that they are wrong. Professor Willis might be considered as the only man who could make guesses on which a moment's reliance could be placed. He did so simply because he had a wonderful intuitive power of putting together evidence in his mind which few possessed, and still more because he never made a guess until he had collected and thoroughly weighed his evidence. He had swarms of imitators whose practice was the very reverse. To begin with they only half understood their subject, and they built upon this defective foundation a superstructure of guesses running ahead of the evidence, and adhered to religiously after proof had been found of their fallacy. To those who have not such intuitive perceptions, the only course is not to guess at all, or to set so loosely by theories that they may, one by one, go to the winds without a moment's regret as fast as adverse evidence presents itself.

Raphael's Variety.

There is not a single emotion of the mind, not a single character of passion known to the moral philosopher which he has not caught, portrayed and varied in a hundred different manners, and yet always within the bounds of propriety. We do not find it recorded of him as we do of Da Vinci, that he constantly frequented public places for the purpose of catching these various expressions. The multiplicity of his pictures, too, proves that he could not have had time for such continued observation, while his designs plainly show that he did not equally stand in need of it. Nature had endowed him with a liveliness of imagination which, transporting him in idea to the scene he was about to represent, however fictitious or remote, and thus making it in some sort real and present, rendered him capable of conceiving and of entering fully into those very emotions which the personages of the story must themselves have felt; nor did this vivid conception of his subject ever desert him till he had portrayed the emotions in question with that air of reality which he had either observed them assume in the countenances of others, or with which he had invested them in his own mind. This rare faculty, so seldom met with even among poets, and so much more seldom among painters, no one ever possessed in a more eminent degree than Raphael. His figures seem to be actually inspired with the different passions of love, desire, fear, hope and joy—seem actually under the influence of anger, or else possessed with a spirit of placability, lowliness or pride, just as best accords with the subject in hand: insomuch that the spectator on regarding the countenances, the expressive looks and gestures of his figures, oftentimes forgets that they are but the work of art; he finds his own feelings excited, chooses his side and fancies himself an actor in the scene before him. There is yet another delicacy of expression to be found in his works, and that is the felicity with which he depicts the various gradations of passion, whereby a man may perceive at once whether they are only just commencing their career, whether they are on the increase or whether they are already on the wane. He had in his intercourse with the world observed these varied shades of passion, and on all occasions he knew how to transfer to the canvas the observations that occurred to him. His very silence is eloquent, "Il cor negli occhi." The slighter movements of the eyes, the nostrils, the lips, or the fingers, serve to indicate the first emotions of passion; the more animated and violent gestures express its intensity, and what is more, these gestures assume a hundred different shapes without ever offending against the laws of nature, and conform themselves to a hundred different characters without ever transgressing the bounds of decorum. His heroes look and act like heroes; his ordinary men, like beings of a lower sphere, and what neither tongue nor pen could ever hope to describe that Raphael contrives to express by a few strokes of the pencil. In vain have numbers endeavoured to imitate him; his figures appear as if under the real impulse of mental feeling, while those of others, with the exception of Poussin and some few more, look as if conscious of acting a part like players upon a stage. In fact, in this exquisite delineation of the various passions of the mind consists the grand merit of Raphael. And if it be acknowledged that this quality called expression constitutes the most difficult, the most philosophical and the most sublime walk of art, who then shall dispute the palm with him?

Early Stained-Glass.

Stained-glass was not only necessary on account of its religious or mystical influence, but to temper the rays of the sun in buildings so full of windows as the Gothic churches, and it improved the architectural effect. Of the specimens the smaller are the more ancient. As the art advanced, portraits and groups of the size of nature were attempted. St. Jerome, who lived toward the end of the fourth century, is the earliest author who speaks of glass in windows. Gregory of Tours, in

the sixth, mentions likewise a glazed window of a church which was broken by soldiers. The poet Fortunatus, who lived at the close of the sixth century, in an account of the church of Paris, now Notre-Dame, gives a pompous description of the stained windows. St. Bennet, abbot of Wiremouth in Scotland, who died in 690, is stated in his life to have gone into France to procure artists to build his church and to ornament the windows with painted-glass. According to Warton, "The first notice of painted windows in a church occurs in a chronicle quoted by Muratori. In the year 802 Pope Leo built a church at Rome, 'et fenestris ex vitro diversis coloribus conclusit atque decoravit;' and in 856 he produces 'fenestras vero vitreis coloribus.' This was, however, a sort of mosaic in glass. To express figures, or what we now call 'painting in glass,' was a very different work, and probably it was brought from Constantinople to Rome in the tenth century with other ornamental arts. Guicciardini, who wrote about the year 1560, in his 'Descrizione de' tutti Paesi bassi,' ascribes the invention of baking colours in glass for church windows to the Netherlanders, but he does not mention the period. It is certain that this art owed much to the laborious and mechanical genius of the Germans, and in particular their deep researches and experiments in chemistry, which they cultivated in the dark ages with the most indefatigable assiduity, must have greatly assisted its operations."

The Kajar Palace of the Persian Kings.

The world-adorning taste of the king caused him to direct that a spot of ground, replete with attractions, and situated about half a league from Teheran, should be laid out in a garden like the celestial Paradise, filled with all sorts of trees and odoriferous plants; and that on the summit of a hill, resembling a mound of pure amber, which commanded that garden, there should be constructed a heart-attracting residence. A decree, therefore, resistless as destiny, went forth that the architects and gardeners should combine to display all their talents on this favoured spot. At that hour, which sometimes happens to fortune's favourites, there was formed a garden of such beauty that the splendour of its roses excited envy in the bosom of the roses of Paradise, and the meandering of its limpid waters outshone those of the fountain of life. Some parts of its surface being unequal the hollows were filled up with sifted earth; and in others the hillocks removed, so as to form a continued and perfect level. Fruit-producing trees of every sort and country, odoriferous shrubs, vernal and autumnal flowers were planted in every part of it. It was crowned by a delightful structure and a Paradise-like abode, ornamented with firm bastions, strong curtains and parapets. In front stood a lake, in the midst of which boiled up a fountain like the Fountain of the Sun, spouting forth waters more lucid than the celestial mirror. At this auspicious moment a firman was also issued to repair and gild the pure dome of the King of Martyrs, the explanation of which is as follows. Through ignorance and the hurry of those who were charged by the late monarch to embellish the celestial dome covering the remains of the Lord of Martyrs at Kerbela, and from their not having accurately calculated the strength of the foundation, the dome gave way, rent asunder, and its gold-coloured bricks began to assume a lunar appearance; but in this same year a faithful superintendent was appointed to remove the heaven-resembling dome, and to build another of such solidity that it should receive no injury in the revolutions of months and years; and that gold of so perfect standard should be used as to remain untarnished in the vicissitudes of days and nights. Praise be to the Almighty that, through the architectural wisdom of the orthodox sovereign, this pure vault became more solid than the empyreal vaults of the sky, and was covered with golden bricks more resplendent than the glorious sun. Thus the inhabitants of the whole earth are continually employed in uttering, with responsive Amens, the just praises of the incomparable sovereign.

Ancient Southwark.

The numerous Roman antiquities found in various parts of Southwark abundantly prove the occupation of the place by that people, but it is most probable that the Roman settlement on the Surrey side of the river was confined within the limits of the guildable manor in Southwark, which extended from St. Mary Overies Dock on the west to Hay's Wharf on the east, and included the north side of St. Olave's (commonly called Tooley Street) from Hay's Lane westward to the bridge, the south side of St. Olave's Street westward from Glean Alley, the site of the Hostelry of the Prior of Lewes, both sides of High Street (formerly called Long Southwark) as far as where St. Thomas's Hospital stood, the west side of High Street nearly to the Town Hall, part of the Borough Market, the site of the church of St. Saviour and Montagu Close, being bounded on the west by the Clink Liberty (anciently the Bishop of Winchester's palace and park), and on the east and south by another of the three City manors in Southwark called the Great Liberty Manor. The guildable

manor had probably been part of the possessions of Earl Godwin, who had a house in Southwark. It is stated in Domesday Book, "De exitu aquæ ubi naves applicabant Rex habuit II^{as} parties, Godwinus Comes tertiam." After the Conquest the guildable manor became the property of the Earls of Warren and Surrey, as appears by the deed dated in 1281, mentioned by Stowe (vol. ii. p. 23), whereby John, the seventh Earl, remitted to Nicholas, abbat of St. Augustine's at Canterbury, and the convent of the same, and their successors, suit to his court of Southwark, which they owed to him for all that messuage and houses builded thereon, which they had of his fee in Southwark, situate upon the Thames between the Bridge House and the church of St. Olave. This manor, afterwards falling into the hands of the Crown, was granted by King Edward III. to the citizens of London by a charter dated March 6, in the first year of his reign. It is there called the "vill" of Southwark. This was the commencement of the authority of the City of London in Southwark. The King's manor was then the property of the Archbishop of Canterbury, and the Great Liberty Manor belonged to the monastery of Bermondsey. The City of London did not acquire these two manors, nor had they any jurisdiction in them, until the reign of Edward VI. The distinction between the three manors in Southwark has not been pointed out by any of the local historians, most of whom have supposed that the City of London had jurisdiction over the whole of the present borough of Southwark from the time of Edward III. Mr. Corner conjectures that the guildable manor was the ancient borough of Southwark, and that in process of time, as the borough extended itself and the buildings spread into the adjoining manors, those manors became also considered parts of the "vill."

Architecture and Painting.

A painter designs his picture, happily for himself, with no thought of constructional or economical difficulties. The shadows which fall so easily from his brush must be constructed by the architect. The latter must see in his mind the effects which he intends to produce, and must build them up, not on canvas or paper, but gradually and painfully by the hands of others. If the result fall short of his expectation, he has no power of alteration, no facilities for heightening lights or deepening shadows. He must be an artist in his design, a man of science in its execution. His science, moreover, must be useful, not merely speculative. Architecture must not only please the senses, she has to justify her very existence by usefulness. Externally she may indulge in grace of form, limited only by the exigencies of climate, construction, and by durability. Internally she must accept the necessity of being bound to combine convenience and fitness with beauty. The arts of design and of building must not clash, but their combination should give a sense of propriety and repose. Architecture must then contrive and construct its artistic effects, remembering always that they must grow naturally out of the circumstances of each case, and that the greatest art conceals its mode of operation. Nothing can be worse than the obtrusion of details, obviously not required but for display, sacrificing the higher qualities of art to a pretentious fussiness. Without ornament, indeed, architecture as a fine art does not exist. Nevertheless, though ornament may be essential, it must be an integral part of that architecture, not a mere *appliqué*, like the beauty-patches of the court ladies of Lely or Kneller. It follows, therefore, that architecture must be studied by those who would practise it, both as a decorative art and as a useful science.

Iron in Fortification.

Many eminent scientific men have looked forward to the time when some material of greater resisting power than stone would be used in works of fortification. One of the most notable instances of this foresight is that of Paixhans, who, writing in 1829, devoted a considerable part of his valuable work, styled "Force et Faiblesse Militaires de la France," to a discussion of the use of iron in fortification. He did not see exactly how it could best be applied, but still he saw that sooner or later it must be used, and he argued by analogy as it were in its favour. He asked why, when a man wears a cuirass to ward off a certain blow, should it be an absurd idea to make a wall wear one so as to be proof against another blow, and whether a fortification of iron would be more strange than bridges of iron, ships of iron, factories and churches of iron, and above all roads of iron; and, he said, what material can be more suitably employed in striving to resist iron projectiles than iron itself? This author also mentions that Gustavus Adolphus proposed to fortify with blocks of iron, and that Daron wished to plate with iron his floating batteries against Gibraltar. And General Totten clearly contemplated the facing a whole work with iron, indeed, the construction of works of iron only, whenever the necessity should arise.

NOTES AND COMMENTS

EVERYONE who is acquainted with the streets around the church of St. Sulpice in Paris is aware of the importance of the trade in producing images and ornaments for churches. The style of the "art" is generally most unsatisfactory, but the works represent an enormous capital. It is commonly supposed that the images which are coloured so glaringly are of plaster or terra-cotta; but other materials are used. It appears that the whole of the oak beams which were found in the old Sorbonne have been utilised for some statuettes. The wood was old and close-grained and well adapted to be fashioned into shape by electric carving machines. For one lot of oak a sum of 30,000 frs. was paid. If the wood was left in its natural state or slightly stained the figures might be commendable, but colours and gold will be applied to them; some will be exalted by vestments and robes of costly materials while others will be adorned with wigs. The bedizenment is necessary, as the statuettes are intended for the South American markets. The Sorbonne was a sort of theological university, and the oak which RICHELIEU may have selected will accordingly be still devoted to ecclesiastical purposes.

If any accidents arise this year in the French cathedrals and churches, they are not likely to be expeditiously remedied. The buildings are, according to the law, public property, but the State is becoming a very unwise owner. Last year the sum assigned by the French Chambers for upholding the cathedrals was 1,080,000 francs, which was much under the average of preceding years. In this year's budget the sum allowed for the same work is only 355,000 francs, or one-third of last year's vote. The sum for churches and presbyteries has been reduced from 3,150,000 francs to 2,000,000 francs. There is a reduction in respect of diocesan edifices from 900,000 francs to 600,000 francs. The sums that are to be paid to the clergy are still more diminished, but we are not concerned with those items. If a priest's death should be hastened by insufficient means, another will be found to take his place. But when buildings even partially succumb to time and weather, unless reparation is immediately undertaken still further expense is entailed. Looking at the subject in its economical aspect, it is evident to all practical men that the resolutions of the French Government are unwise. But what else is to be expected from any party of men who have had no experience with property of their own, and cannot therefore be aware that buildings are not to be trusted to take care of themselves?

WE have already referred to the competition for an Evangelical church in Mayence, which was a fiasco. Five architects possessing so much experience in ecclesiastical buildings as to make them specialists were invited to prepare plans, but not one of their designs could be carried out for the sum proposed, viz. 35,000*l*. The church authorities then opened the competition to all Germany, or all Europe if desired, with no more satisfactory result. There are many grades of authority who have a voice in the selection of plans, and it is supposed that all the time it has been decided that the design of an architect who has taken no part in any of the contests will be executed. A resolve of that kind would not be in accord with old-fashioned German sincerity, but since Prince BISMARCK appeared on the scene many things are done which are supposed to be imitations of his diplomatic feats, but which at one time would have received a very different sort of designation. It will be a bad day for German architects if Bismarckism becomes an influence in arranging competitions.

WHEN it was known that Dr. CHARLES WALDSTEIN was a candidate for the Slade Professorship at Cambridge it was taken for granted that other competitors would have little chance of the prize. Dr. WALDSTEIN has been reader on classical archaeology since 1884. In the time that has elapsed he has done useful work, and has given an impetus to the study. In America he is no less esteemed, as was shown by his appointment as director of the American explorations in Greece. The Slade Professor is elected for

a term of three years, but is eligible for re-election. He is required to deliver annually in the University during full term a course of not fewer than twelve lectures on the history, theory and practice of the fine arts. The stipend of the chair is about 350*l*.

FRENCH critics have of late years instituted many comparisons between the Louvre and the National Gallery. They generally recommend that the officers who have charge of the pictures in Paris should be periodically sent to Trafalgar Square in order to become acquainted with the most effectual methods of displaying treasures. It is commonly supposed that the Louvre possesses countless masterpieces rolled up in the cellars and attics, which are concealed owing to the indifference of the curators. The truth is there is not enough wall space in the Louvre for all the pictures which the nation possesses. More satisfaction would be derived from it if a different arrangement were adopted. Hitherto history has been supreme, and it compels visitors to gaze on acres of canvas which afford evidence of the existence of many painters but without exciting the least pleasure. The Salon Carré shows what can be done by departing from the order of time and arranging pictures in the way that is most effective. That is the only gallery which many visitors care to behold. Another attempt of the same sort has been tried this week. The best works of the early Italian masters CIMABUE, GIOTTO, CARPACCIO, JOHN BELLINI, FRA ANGELICO, MANTEGNA, have been placed together and the result is a surprise. Most of the pictures seen are old residents, but hitherto they were overlooked amidst a crowd that was remarkable for age alone.

FOR a long time the financial condition of house property in Rome has been most unsatisfactory. There has been overbuilding, and the mortgage banks and other creditors, dissatisfied with the absence of return on their loans, have been putting up a great many houses for compulsory sale, although it is well known that purchasers are not likely to be present. In most cases, unless the houses are placed in some central locality, no tenders are forthcoming, and the upshot very often is that the mortgagees themselves finish by becoming the owners. It is no wonder that there is a tendency to panic in Rome, and a risk that buildings will be considered as the least profitable of investments. One of the companies that deal in house property has been trying to get up evidence to prove that there is much in Rome which should inspire hope. Buildings containing 3,850 lodgings and 975 shops owned or managed by the company have been adopted as a field of investigation. It was found that from the year 1892 to 1893 the premises unlet fell from 28.42 per cent. to 21.69 in the case of lodgings, and from 35.19 to 32.65 per cent. for shops. These figures show that on the whole there has been an advance; but they do not represent a uniform state of things, because in some parts of Rome there are scarcely any apartments empty, while in others they are very numerous. Upon every 100*l*. of rent due by tenants, 94.40 were actually collected in 1892 and 97.49 in 1893, which is another sign of improvement. The average degree of occupancy of the inhabitants of Rome is reckoned at .75 rooms for every 100 persons living in families, so that with a population of 450,991 inhabitants there would be needed 338,244 rooms, while their number amounts to 362,000. Not all of these are however actually tenable, because a good many lodgings are neglected or whole buildings are closed up by the owners so as to avoid paying the Government taxes, but the excess is self-evident and shows what a moderating effect it must have upon rents.

THE late RUDOLF SPRINGER, the German architect, whose archaeological investigations were appreciated by his countrymen, was a native of Frankfurt. From time to time he made many valuable presents to the collections of his native city. At his death he bequeathed several examples to the trade museum of Japanese pottery, lacquer and metal-work, especially of seventeenth and eighteenth-century date. These have been received and are now arranged in satisfactory positions.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

A MEETING of the Institute of Architects was held on Monday evening, Mr. F. C. Penrose, president, in the chair.

The deaths were announced of the following members:—Messrs. T. E. Bridgen, Arthur Lett and Ewan Christian.

The PRESIDENT proposed that the condolences of the Institute should be sent to Mr. Christian's widow and family, which was unanimously agreed to.

Mr. T. W. ALDWINCKLE read a paper, of which we give the following short abstract, on

Fever Hospitals.

Mr. Aldwinckle said he wished to preface the paper with two preliminary remarks. In the first place, very much in it as to the requirements of fever hospitals would necessarily apply to hospitals of all kinds, being general principles of sanitation; and in the second place, as they were at the present time only upon the threshold of the vast and intricate subject of provision for infectious diseases, the paper had been written rather in the spirit of inquiry than of dogmatism, not pretending to lay down hard-and-fast rules, but rather as offering suggestions, based to some extent upon practical experience, for the consideration of those who might be interested in the subject. It was difficult to overestimate the importance of the subject which they were to consider that evening. Infectious disease might be regarded as an invading and powerful enemy, ever ready to enter the dwelling or the city and to cause widespread ruin and destruction. Past history told us only too forcibly how powerful and destructive this enemy has been in times now happily gone by, when its inroads were unchecked by the fortifications of medical science and legislative provisions, and it was well within the province of architecture to lend her powerful aid to the researches and efforts of medicine in this defensive war against a common foe. The architect who would join in this humane crusade must, in order to be useful and successful, make himself intimately acquainted with the minute detail of the inner working of a fever hospital, and he could not do better than always bear in mind the following pregnant words from Sir Douglas Galton's book on "Hospital Construction."

"Cleanliness and fresh air do not so much give life as they are life itself to the patient. Cleanliness—clean air, clean water, clean surroundings—and a fresh atmosphere are the true safeguards against infection, segregation by ample floor and cubic space, ample ramparts of fresh atmosphere, rather than segregation by walls and divisions. You cannot lock in or lock out the infectious poison. You can air it, diffuse it and clean it away."

The general awakening of the public mind to the absolute importance of the isolation of persons suffering from infectious diseases was quite a recent one, as evidenced by the fact that thirty years ago there was in this country a complete absence of any organised system of infectious hospitals, and that London at that time possessed only two, viz. the London Fever Hospital at Liverpool Road, Islington, and the Smallpox Hospital at Highgate, both institutions being entirely supported by voluntary subscriptions. Some of the general hospitals received fever patients under conditions of very imperfect isolation, failing which infectious cases were sent to the workhouse, with results which can be easily imagined. As a natural consequence, the majority of patients suffering from fevers were treated in their own homes, and the general community lived on peacefully, utterly oblivious of the fact that infectious diseases were rampant in its midst, and only quickened into a slight sense of interest by occasional epidemics. The one great principle that an infectious case treated in its own home generally became a centre of infection had only been recognised by the few.

The Sanitary Act of 1866 first gave powers to the local authorities to build, or otherwise arrange for, permanent or temporary hospitals for infectious diseases, and these powers have been considerably enlarged by the Public Health Act, 1875, and the Isolation Hospitals Act, 1893.

The site should be, if possible, just outside the town or village for which it is intended. The question of transport of the patient was not so serious a difficulty as to outweigh the great advantages to be derived from the hospital having open fields rather than houses as its surroundings. Good ambulance arrangements would overcome all difficulties as to transport. The land should be capable of good drainage and there should be the means for a good and ample water-supply. The land should stand at a fairly high level and a gentle fall towards the south is a distinct advantage. If there were any trees on the site when purchased, those on the north and east boundaries, at least, should be left standing if possible. There should be two entrances to the hospital, one the "infected entrance" and one the "non-infected entrance," both controlled from the same porter's lodge. A wide roadway should run round the whole of the site, as a neutral zone to separate the hospital from the surrounding property. The axes of the ward pavilion should be as nearly as possible north-east and south-west, in order to provide for the maximum quantity of sunlight and the minimum of shade. This was of the utmost importance and should be carefully borne in mind in the selection of a site. The ward pavilions should not, where practicable, be of more than one storey in height. This might necessitate the purchase of a larger site than otherwise, but the compensating advantages were many. He did not suppose that any experienced hospital architect would, by choice, place fever wards one above the other, necessitating, amongst other evils, much traffic up and down staircases, to say nothing of the obvious objections from a sanitary point of view, so that considerations of land area can be the only reason. It was pointed out in this connection that the distance between the one-storeyed pavilions can safely be less than that between those of the two storeys, so that the expansion of the plan need not be so great as would at first appear. In the former case 50 feet will be sufficient, whereas in the latter case the width should not be less than twice the height of the pavilions, and would thus be not less than 65 feet. The whole of the several buildings of an infectious hospital should be completely isolated, and stand perfectly free, without communicating corridors or covered way of any kind. This was not suggested as an experiment, but as the result of personal observation in the case of several excellent hospitals, such as the Eppendorf Hospital, Hamburg; the Moabit Infectious Hospital, Berlin; the Frederichain Hospital, Berlin; the Urban Hospital, Berlin; the Belvidere Hospital, Glasgow; the Grafton Street Infectious Hospital, Liverpool. Others can be named, of which, however, I cannot speak from personal observation, such as the Epidemic Hospital, Copenhagen; the Ladywell Sanatorium, Salford; the Heathcote Infectious Hospital, Leamington, &c. It will doubtless be admitted that in an infectious hospital complete and absolute isolation of each ward pavilion, at least, is most desirable, and there should be good reasons adduced for in any way impairing such isolation by the introduction of communicating corridors, even with open sides. It was stated by some hospital authorities that these covered ways are necessary in order to protect the staff from the weather; but, apart from the fact that they are wholly inefficient for such a purpose, the authorities at the hospitals mentioned as being without corridors or covered ways all assured him that the staff experienced no ill effects or inconvenience whatever from their absence. The complete isolation of the buildings is recognised and prepared for, the nurses and others dress accordingly, and the arrangements for conveying hot food from the kitchen to the wards are so well considered and complete that the food is, in all probability, hotter when it reaches the wards than in the other cases. There should be a clear space of at least 3 feet between the underside of the ground floor of all wards and the adjoining yard level, and the space thus left underneath the floor should be paved with tarpaving or some equally impervious material, laid in such a manner that the rain-water shall naturally drain off the same. The ward pavilions for diphtheria or enteric fever should be separated at as great a distance as possible from those for scarlet fever. The isolation wards should be well separated from the remainder of the hospital. The official department and the kitchen and stores should be centrally situated, and the stores should be as near as possible to the "non-infected entrance." The staff quarters should be quite free from, and unsurrounded by, the ward pavilions or other infected buildings. The three classes of the subordinate staff in a large hospital, viz. nurses, female servants and male servants, should have separate and distinct homes, each home being under the resident control of the principal officer responsible for its discipline. The laundry should be as free as possible from the hospital proper and from the staff quarters. No infected building should be nearer than 40 feet to the boundary, nor to any other building, infected or otherwise, in the hospital. In the acquisition of a site for a fever hospital the question arises as to the number of beds per acre that can safely be provided. In the plan B, issued by the Local Government Board, the hospital of 8 beds is placed

upon one acre of land. For larger hospitals I do not think that the maximum should exceed 20 beds per acre. At the Belyidere Hospital, Glasgow, there are 17 beds to the acre; at the Grafton Street Infectious Hospital, Liverpool, 34 beds; at the Moabit Infectious Hospital, Berlin, 40 beds. The older hospitals of the London Asylums Board show a somewhat higher proportion, the Eastern Hospital having 40 beds per acre, the Western Hospital 36 beds, the South-Western Hospital 47 beds, the South-Eastern 42 beds per acre; while their hospitals recently built or now projected bear the following proportion:—North-Eastern 22 beds, Fountain Temporary Hospital 40 beds, Brook Hospital 16 beds, Park Hospital 28 beds, and the Fountain Permanent Hospital 19 beds per acre. The temptation was very great to raise the percentage of beds where the land is expensive, but it should be borne in mind that land is at once the cheapest and most permanent part of the expenditure upon a hospital. This question led to another and a very important one, viz. as to the maximum number of beds for which an infectious hospital should be built. The requirements of large towns necessitated the provision of a large number of beds; but it was an open question, most suitable for discussion, whether the aggregation of large numbers of acute infectious cases upon one site is desirable, and whether it would not be a preferable course to arrange hospitals for a smaller number of beds, and to increase the number of such hospitals in order to provide for the total number of beds required. As an illustration, if the population requires a provision for 400 beds, he would suggest the erection of two hospitals for 200 beds each rather than one for 400 beds; and where the required provision is for 750 beds, three hospitals of 250 beds each might be preferable to two of 375 beds. Indeed, a maximum of 300 beds suggests itself as desirable. It is usually less difficult to obtain sites for small hospitals than for large ones, and the hospitals being distributed would, in the case of large towns, render them more easy of access. For present purposes they could divide fever hospitals into three classes, viz. *a*, small isolation hospitals, suitable for groups of villages or small towns; *b*, hospitals not exceeding 100 beds; *c*, hospitals exceeding 100 beds.

English communities nowadays recognised the advantage of isolation hospitals as a means of preventing the spread of infectious diseases from persons who cannot be properly isolated in their own homes. But too often the provision of such hospitals is put off until some infectious disease is immediately threatening, or has actually invaded, a district. It cannot be too clearly understood that an isolation hospital, to fulfil its proper purpose of sanitary defence, ought to be in readiness beforehand. During the progress of an epidemic it was of little avail to set about hospital construction. The mischief of allowing infection to spread from first cases will already have been done, and this mischief cannot be repaired.

Large villages, and groups of adjacent villages, would commonly require the same sort of provision as towns. Where good roads and proper arrangements for the conveyance of sick have been provided, the best arrangement for village populations was by a small building accessible from several villages; otherwise the requisite accommodation for, say four cases of infectious diseases in a village might at times be got in a fairly isolated and otherwise suitable four-room or six-room cottage which has been acquired by the Sanitary Authority, or by arrangement made beforehand with some trustworthy cottage-holders, not having children, that they should receive and nurse, on occasion, patients requiring such accommodation.

In towns, hospital accommodation for infectious diseases was wanted more constantly, as well as in larger amount, than in villages; and in towns there is greater probability that room will be wanted at the same time for two or more infectious diseases, which have to be treated separately. The permanent provision to be made in a town should consist of not less than four rooms, in two separate pairs, each pair to receive the sufferers from one infectious disease, men and women of course separately. The number of cases for which permanent provision should be made must depend upon various considerations, among which the size and growth of the town, the housing and habits of its population, and the traffic of the town with other places are the most important.

For a town the hospital provision ought to consist of wards in one or more permanent buildings, with space enough for the erection of other wards, temporary or permanent. Considerations of ultimate economy make it wise to have permanent buildings sufficient for somewhat more than the average necessities of the place, so that recourse to temporary extensions may less often be necessary. And in any case, it is well to make the administrative offices somewhat in excess of the wants of the permanent wards; because thus, at little additional first cost, they will be ready to serve when occasion comes for the wants of temporary extensions.

Plans illustrating the sanitary requirements of small hospitals for infectious diseases were shown, and the principal hospitals here and abroad described at length.

Mr. Gordon Smith proposed a vote of thanks to Mr. Aldwinckle for his paper, which was seconded by Dr. McCrombie, and supported by Dr. Goodall, Mr. E. T. Hall and Dr. Downs.

Mr. Aldwinckle replied, and the meeting was adjourned.

WESTMINSTER AND ITS DIVISIONS.

WESTMINSTER is described in Domesday as a manor within the hundred of Ossulston, in Middlesex, pertaining to the church of St. Peter. The earliest account of its boundary appears in the charter of King Edgar, of the year 951, which is to be found in the original Saxon in Widmore's "Enquiry into the time of the foundation of Westminster Abbey," and of which reference the translation is as follows:—

"First up from Thames, along Merfleet to Pollen Stock, so to Bulinga fen; afterwards from the fen, along the old ditch, to Cowford. From Cowford up, along Tyburne to the broad military road; following the military road to the old stock of St. Andrew's Church; then within London fen, proceeding south on Thames to mid stream and along the stream by land and strand to Merfleet."

Such then, according to this charter, were the limits of Westminster in the year 951. Most of the names mentioned in it have been lost in the changes that have taken place.

"Up from Thames" can have reference only to the Thames at London. London at that time might be understood to have its westerly termination at the London fen mentioned in the charter. This fen probably assumed the name of Flete Dike in after times, in consequence of becoming contracted to a narrow channel by a progressive accumulation of soil. The boundary, according to the description in the charter, as is evident towards its conclusion, also commenced higher up the river than where it was bordered by the strand, at a part called Merfleet, agreeing with the marshy site of Whitehall, along which it proceeded to Pollen Stock. Pollen Stock may have been the termination of the high ground, near the river, on which the monastery was placed. The boundary then continued to Bulinga fen, which also agrees with the ancient marsh of Tothill Fields, reaching from the neighbourhood of the Abbey to the old ditch, now the King's Scholars' Pond Sewer; along which ditch the boundary continued to Cowford, and from thence up along the Tyburne stream to the broad military way, now Oxford Street. Thus far we seem precisely to follow the boundary described in the charter. It afterwards proceeded along the military road to the old stock of St. Andrew's Church, being in the line of Oxford Street and Holborn, and then took a southerly direction within the London fen, answering to the situation of the Flete Dike, to the mid stream of the Thames, and along that stream by land and strand to Merfleet, where the boundary commenced.

A subsequent description of the boundary of Westminster appears in the decree of 1222 for terminating the dispute between the Abbey and the See of London respecting the ecclesiastical franchise of the conventual church of St. Peter. Widmore observes that, "with respect to its exemption from episcopal jurisdiction, that we know was not fully adjusted till the year 1222;" and again, that "the precinct of the Abbey, and the whole parish of St. Margaret, at that time larger than at present, were declared exempt from the Bishops of London, and made a peculiar jurisdiction."

Of the prescribed limits in 1222 it may generally be remarked that westward they quite accord with the explanation given of those of the year 951; but that eastwards, towards the City of London, a great difference appears between the boundaries of the two periods.

The decree of 1222 is inserted at length in Wharton's "Historia de Episcopis," &c., the title declaring it to be concerning the exemption of the monastery of Westminster and of the parish of St. Margaret from the jurisdiction of the See of London.

It is declared in the decree that Westminster, then entitled the parish of St. Margaret, "begins, on the one part, from the water of Tyburne running to the Thames." This watercourse is still continued under the name of the King's Scholars' Pond Sewer, with little variation of its ancient line from the west side of Stratford Place. Stratford Place was the site of the Banqueting-house connected with the city conduits adjoining the ancient village of Tyburne, situate about the end of Marylebone Lane, where the line abuts on the north side of Oxford Street. After crossing Oxford Street, the watercourse proceeds along South Molton Lane, and along Bruton Mews, Bolton Row, and White Horse Street, into the Green Park, passing by Buckingham Palace and the west side of the ancient Tothill Fields to its outlet at the Thames, about a furlong west of Vauxhall Bridge.

In this decree of 1222, the boundary is described to be, on the other part, "as the king's highway stretches towards London to the garden of St. Giles's Hospital," which is pre-

cisely the present boundary of that part of the Westminster district to the east end of Oxford Street, "and thence as the way beyond the said garden extends to the boundaries dividing Mersland and the parish of St. Giles." This way, according to Parton, always passed from Oxford Street, bordering the hospital garden to the division of the Mersland, in the line of Crown Street, West Street and Castle Street. The boundary is continued "thence according to the separation of the gardens of Tholi and the monks of Westminster, to the house of Simon the weaver (saving the question of the monks of Westminster, concerning the land from that Simon's house to the chapel by the Church of the Innocents), and from the house of the same Simon, as the king's highway extends towards Westminster to the rivulet of Ulebrig running into the Thames."

Two circumstances mentioned here guide to the situation of Simon the weaver's house. The first is the piece of ground between the said house and the chapel by the Church of the Innocents, which was another title, according to Stowe, for the ancient church of St. Mary at the Strand. Noorthouck states that this church "was then situated on the south of the Strand, where the east end of Somerset House is placed." The other circumstance guiding to the situation is that "from the house of the same Simon" the boundary of St. Margaret's parish proceeded, "as the king's highway extends towards Westminster to the rivulet of Ulebrig running into the Thames." Ulebrig was the Ivy Bridge in the Strand, at the end of the present Cecil Street, and was the only bridge in the direction here mentioned.

A piece of ground, uncovered in Aggas's "Plan of London" in Elizabeth's reign, but now built upon, such as that represented to have been between the house of Simon the weaver and the chapel by the Church of the Innocents, occurs between Drury Lane, at the end of White Hart Yard, and Somerset House, and from the house of Simon so situated in Drury Lane to Ivy Bridge the direct way was nearly along that part which forms White Hart Yard and Exeter Street, and which at the period of the decree was probably part of a broadway in front of the Savoy, such as roads commonly were at that time, comprising the breadth now occupied by two streets. The sites of Burleigh House and of other buildings erected afterwards on the north side of the Strand were, probably grants of the large waste taken from the sides of the common way, when a regular road began to be formed along the Strand in the year 1353.

The declaration of the limits concludes thus:—"And so, whatever is contained by the Thames, on one part, and these bounds belongs to the parish of St. Margaret, except the church and cemetery of St. Martin. And beyond these before-mentioned bounds the districts of Knightsbridge, Westburne, Padyngton with its chapel and their appurtenances belong to the parish of St. Margaret aforesaid."

This decree entirely excludes from the Westminster franchise towards the east all the precinct of the Savoy and the entire parishes of St. Mary-le-Strand and St. Clement Danes, with the portions of the parishes of St. Andrew and St. Giles which were included within the boundary of 951, and it confines Westminster in 1222 to the then single parish of St. Margaret, at that time comprising, together with the existing parish of that name, all the present parishes of St. Paul, Covent Garden, St. Martin in the Fields, St. Anne, St. James, St. George, Hanover Square, and St. John the Evangelist. But westward, in addition to what was comprised in the charter of 951, this decree of 1222 declares the manor of Knightsbridge, Westburne and Paddington, all which were distant from the described boundary of Westminster, to belong to the parish of St. Margaret.

A further difference between the words of the charter and those of the decree, without causing any variation in the western limit, also claims attention. In the charter of 951 the boundary is said to be "by the old ditch to Cowford, from Cowford up, along Tyburne, to the broad military road." But in the decree the western boundary commences with "the water of Tyburne running to the Thames." This, if no change had occurred, would have been, according to the first description, the water of Tyburne running to the old ditch by the Cowford, the ford implying that there was then a continuation of the ditch each way. The difference between the words in the two descriptions is to be attributed to the old ditch being filled up towards the spot where it had at the earlier period been forded, and as, by the form of the land, the Tyburne stream could never have taken any other course than towards the old ditch near James Street, the ford seems to have been in the vicinity of the road which then led from the north by the line of the present front of Buckingham Palace. The old ditch appears by the form of the land to have continued eastward of James Street, passing along the low ground where now is the ornamental water of St. James's Park. The old ditch, by being filled up near the place of the ford, would be divided into two separate lengths; and the southern portion, receiving the water of Tyburne, would with it become a distinct water-course from the Tyburne springs to the Thames, as described in the decree of 1222.

It may be interesting to compare the descriptions of 951 and 1222 with the quantity of land which was comprised in Westminster at the time of the Domesday survey; in computing which quantity we must not be unmindful that there is much difference of opinion respecting the quantity contained in a hide of land. A hide is generally supposed to have been as much as was sufficient for the cultivation of one plough, and this is stated by some at less than 40 acres and by others as high as 120 acres. The measure of the hide probably varied, as was common at those early periods, according to the custom of different places. A similar mode of estimating the quantity of land is still practised in Greece between the proprietors and tenants of farm lands. The landlord there "provides each family on his estate with a cottage, a yoke of oxen, and sufficient seed for one Zengaria" (literally, yoke, used to designate an extent of from 50 to 60 acres in Eubœa, of 100 and upwards in Attica and other parts), the landlord taking a portion of the produce instead of a fixed rent.

In regard to the hide, an approximation of the average quantity may perhaps be obtained by examining a tolerably well ascertained manor in the same county containing a large number of hides. Such an opportunity is afforded in the manor named Stibenhede in Domesday, which comprised the present parishes of Poplar, Limehouse, Stepney, with its three hamlets of Radcliffe, Mile End Old Town and Mile End New Town, Shadwell, Wapping, St. George in the East, Whitechapel, Spitalfields, Bethnal Green and Stratford-le-Bow. It also appears to have comprised Bromley, which was environed by other parts of Stibenhede, and was not named as a separate manor in Domesday. This fact affords pretty good evidence of its having been extracted from the larger manor of Stibenhede subsequent to the Domesday survey, and afterwards given to the convent of St. Leonard by Sir Ralph Roseline, as he is named by Speed, or Josseline, as he is named by Newcourt.

The manor of Stibenhede is stated in Domesday to have contained 59½ hides, which are enumerated as follows, namely, 32 hides of land held by the Bishop of London, 5½ held by Hugh de Berners, 5 by the wife of Brien, 3½ by Ranulf Flambard, 1 by William de Ver, 1½ by Engelblue, 1½ by the Bishop of Lisieux, 1½ by William the chamberlain, 1 by Aluric Chacepul, 4 by Robert Fasiton, and 3½ by Robert, son of Rozelin, probably predecessor of Roseline, who gave the manor of Bromley to the convent of St. Leonard.

The map containing all the parts which composed the original manor of Stibenhede, on a scale sufficiently large and distinct for judging of their proportions, is that of London by G. & W. Greenwood, dated August 31, 1830. The quantity, as taken upon this map, of the land which constituted the manor of Stibenhede amounts to 4,763 acres; and this being divided by 59½, the stated number of hides in the manor, gives for each hide nearly 79½ acres. But, as exact agreement cannot be expected in estimating measures of these distant periods, it may be sufficient, for the present purpose, to consider the hide of this district to have contained, on the average, eighty of our present acres.

With respect to the manor of Westminster, it is stated in the Domesday register that the Abbot held thirteen hides and a half, which "was and is now in the demesne of the church of St. Peter of Westminster;" and that Bainiard, also in the same demesne, held three hides of the Abbot, making together sixteen hides and a half in the manor; which, in order to comprise the whole of the district contained within the prescribed limits of Edgar's charter, would require the sixteen hides and a half to contain nearly seventy acres each.

It is to be noted that the district of Westminster, as bounded in Edgar's charter of 951, was at the time of the Domesday survey surrounded by the manors of Eia, Lilestone, Tyburne, &c.; and that Knightsbridge, Westburne and Padyngton, stated in the decree of 1222 as belonging to the parish of St. Margaret, are not mentioned by those names in Domesday. Whether these were then portions of other manors it is perhaps not possible now to ascertain. According to Dart, Paddington occurs as an appendage to the convent of Westminster in a charter of King Edgar. He says also that King Stephen afterwards confirmed to them this manor, as did likewise King Henry II.; and that this manor with the rectory of the church continued in the possession of the convent till the time of the dissolution. Newcourt observes that at the dissolution of monasteries, King Henry VIII. in 1541 made Westminster an episcopal See, the church of St. Peter a cathedral, and Westminster a city, allotting the whole county of Middlesex (the parish of Fulham only excepted) for the diocese; and that King Edward VI. in 1550 dissolved this bishopric and restored the county of Middlesex again to the See of London. Newcourt further says that the manor and rectory of Paddington (which of old did belong to the monastery of Westminster) were by Edward VI., upon his dissolving the Bishopric of Westminster, given to the Bishop of London and to his successors for ever. Westminster Abbey was thus deprived of the manor of Paddington, together with the rectory of the

parish, but retained the manor of Westburne, which was within the parish of Paddington. The circumstance of the manor of Knightsbridge being also reserved to the Abbey and not forming a part of Paddington, accounts for its remaining annexed to the parish of St. Margaret, although considerably distant.

It is probable that after the Domesday survey, and previous to the decree of 1222, the part between the Flete Dike and Temple Bar had been separated from Westminster and added to the liberties of the City of London. The supposition that the Fleet was once the London fen was corroborated by an inspection of the spot where the remains of a steep bank were found at the side of Seacoal Lane, from the foot of which steps ascended to Green Arbour Court and Bishop's Court, both on the level of the Old Bailey, along which level the City wall passed in the line of Newgate. The summit of the step was about 20 feet above that part of Seacoal Lane, and from thence the descent to Farringdon Street (the line of the ancient Flete Dike) was about 16 feet, thus making the whole height from the level of Farringdon Street to the top of the acclivity about 36 feet. The level of the low ground having by the natural operation of time been much raised, renders it probable that the height of the bank had formerly been greater than has been stated. The distance of the steps from the middle of Farringdon Street was about 300 feet, and assuming that there was the same distance to a bank on the other side of Farringdon Street, the breadth of the fen between the banks would be about 600 feet. The most ancient causeway over the Fleet was undoubtedly that which was in the line of Ludgate; the other in the line of Holborn Bridge not having been requisite until, according to Stowe, an entrance to the City was made through the Newgate about 1135.

If the Baniard of Domesday was the Baron of Castle Baynard, the three hides held by him under the Abbot of Westminster manor would in all likelihood be in that part of the Westminster desmesne which lay nearest to the castle and which adjoined the Fleet; the three hides corresponding very nearly to that portion of the district affirmed to Westminster in Edgar's charter of 951 and excluded in the decree of 1222. Baynard, according to the quotation in Stowe's Survey, came to England with the Conqueror, and built Castle Baynard. His successors became chief bannerers of London, which makes it not improbable that a great part of what he held under the Abbot might in consequence of that municipal connection have been alienated from Westminster, and merged in the liberties of the City of London. Other considerable changes must have taken place soon after the Conquest, when, as stated by Leland, Matilda, Queen of Henry I., in 1117, founded the hospital of St. Giles in the Fields of London, with an oratory, which ultimately became the church of a parish of that name. The parish of St. Clement Danes is believed originally to have comprised, together with the present parish of that name, those also of St. Mary-le-Strand and the precinct of St. John the Baptist of the Savoy. That St. Clement Danes was appurtenant to Westminster in the time of the Conqueror appears by his charter of 1067 to the Abbey, wherein he "charges Hamo, his steward, with unjustly seizing on the church of St. Clement Danes in the Strand (violenter et injuste sibi usurpavit), and which he had himself caused to be restored." Newcourt says that Henry II. gave the church of St. Clement Danes to the Knights Templars, which, of course, took place prior to the end of his reign in 1189. The Abbey must then have been dispossessed of this benefice, and we find it wholly omitted as belonging to Westminster in the decree of 1222. Portions of the parishes of St. Clement Danes and St. Mary-le-Strand have, since the year 1222, been again annexed to the liberties of Westminster; but the exact period of the annexation does not appear to have been clearly ascertained. It was probably coincident with the subsequent establishment of the Savoy manor, formed out of the other portions of those parishes.

Widmore (who must be esteemed a valuable authority in consequence of having had within his reach, as librarian to the Dean and Chapter of Westminster, documents not generally accessible, and having been, as Nightingale observes, "more-over a man of learning"), says that "the famous Geoffrey de Mandeville, who distinguished himself at the battle of Hastings, mentions his having buried his first wife Athelais in those cloisters, and his intention to lie there himself;" and again, that "Athelais, the first wife of Geoffrey de Mandeville, and probably he himself too, was buried in the cloisters; in consideration of which he gave to the monastery the manor of Eye, between Westminster and Chelsea."

The manor of Eia, in Domesday, is said to be held by Geoffrey de Mandeville, and to have answered for ten hides. The space between the King's Scholars' Pond Sewer and the Ranelagh Sewer, from the Uxbridge Road at Bayswater to the Thames, measures about 890 acres, which would make ten hides of 89 acres each. Eia, after the date of Domesday, appears to have been divided into the three manors of Neyte, Eubery and Hyde; for in 1342 (15 Edw. III.) "Neyt" is named in a

special commission of sewers; and Widmore says that in 1362 Abbot Litlington "improved the estate of the convent at Hyde, now Hyde Park;" and that "Litlington died November 29, 1386, at the manor house of Neyte, near Westminster, at that time thought a good building, for the Duke of Lancaster, styling himself King of Castile, desired leave of the abbot to reside there during the sitting of a Parliament at Westminster." In the dispute which in 1592 was laid before Lord Burghley as High Steward of Westminster, concerning Neat and Eubery "farm towards Chelsea," being claimed by the inhabitants of Westminster as Lammas grounds, 108 acres are stated to lie in Neat and 430 acres in Eubery farm. To these there would be some addition of land not deemed to be Lammas grounds, which, with the Hyde manor, would together be the quantity rated in Domesday to the original manor of Eia. It appears by Widmore that the Hyde manor was not enclosed as Hyde Park until after it was obtained by Henry VIII. in 1536.

The Act confirming the exchange to the king of lands, some of which afterwards formed the portion of Hyde Park lying north-east of the Serpentine river, is the 28th Henry VIII. c. 49, and is inserted among the statutes of the Realm, published by the Commissioners upon the Public Records. The conveyance, as recited in the Act, is dated "the first daye of July in the 28th yere" of the king's reign; and by it the Abbot and convent transferred to the king the manor of "Nete," which is described to be "in the townes and parysshes of Westm' and Seynt Martyns in the felde;" also the manor of "Hyde" and the manor of "Eybury," with which last "Eye Brydge" is named. The Eye is also named in describing the Nete lands. "Conduyte mede" (on which Conduit Street and Hanover Square have since been built) is mentioned as being east of "Bryk close," belonging to Eyebury. Eye, as the name of a water-course (previously entitled the Tyburne), seems to have been derived from Eia, of which manor it was the boundary on the east side, from the Thames to the Tyburne Road. The name appears to have been afterwards converted into that of Aye Brook, which gave the corrupt name of Hayhill to the steep ascent on the side of the brook.

Nete, Eybury and Hyde must have been constituted manors out of the original manor of Eia, when, according to a common practice, as Sir Henry Ellis observes in speaking on the subject of multiplying manors, "the lord divided his manor, as the State had divided the kingdom, into two parts; the one he retained for his own support was partly cultivated by his villeins and copyholders and was called his demesnes [dominion], the other part was parcelled out among his dependants, who returned him their services. Such was the history and such the multiplication of manors in the times immediately succeeding the Norman conquest. The statute of Quia Emptores [18 Edw. I.] in 1290 put an end to their further increase."

The convent of Westminster obtained the manor of Eia, as Sir Henry Ellis observes, "close upon the time when the [Domesday] survey was taken," the gift of it by Geoffrey de Mandeville to the convent being confirmed by King William the Conqueror; yet it is remarkable that in the decree of 1222, giving the boundaries of Westminster (or of St. Margaret's parish, as it is there termed), the manor of Eia is not comprised within the franchise of Westminster, although that manor was situated between the described western boundary and other parts belonging to St. Margaret's parish distant from that boundary. An attempt to include the manor of Eye in the franchise of Westminster was resisted on the part of the Crown in 1345, as appears by an order "amongst the records of the Court of Chancery, kept in the Tower of London, (to wit) the Patent Rolls of the eighteenth year of the reign of King Edward, after the conquest the Third," for inquiring of lands which were of Edmond Barber, "in Eye, near Westminster, in the county of Middlesex," which lands, in consequence of his having been adjudged to be hanged for the murder of his brother, had been seized by the Abbot and monks of Westminster. No statement of the result was obtained, but it is quite clear that in 1536, when the manor was transferred to King Henry VIII., it was then deemed to be in Westminster and in the parish of St. Martin in the Fields, being so expressed in the Act, 28 Henry VIII. cap. 49, for confirming the exchange.

It has been shown that in 951 the district of Westminster extended from the Tyburne watercourse on the west to the Flete Dike on the east, the Tyburne Road and Holeburne being the boundary on the north and the Thames on the south, and that in 1222 the western boundary was the same Tyburne watercourse, while the eastern boundary excluded a part of what had been comprised in the charter of 951, viz. that portion of St. Giles and the whole of the parishes and places lying between the Flete Dike and the present parishes of St. Paul, Covent Garden, St. Martin in the Fields and St. Anne. On the north-west, beyond the boundary, there were also appended to the parish of St. Margaret the lands of Knightsbridge, Westburne and Paddington.

In 1393 a charter was obtained from King Richard II., in the seventeenth year of his reign, which is enrolled in the

Exchequer. It is affirmed in the charter that the Abbot, in right of his monastery, was seized of "the manor of Westminster, in the town of Westminster, and in the parish of St. Martin in the Fields, the blessed Mary of the Strand, and St. Clement Danes without and near to Temple Bar," which were by that charter so "declared, granted and confirmed," with all fines, forfeitures, &c.

The limits of the Westminster franchise were finally and more explicitly defined in letters patent of the second of James I. (August 3, 1604) to be "within all the aforesaid manor and city of Westminster, and within the [then] parish of St. Margaret there, and within the [then] parish of St. Martin in the Fields, and the parish of St. Clement Danes without the Barr of the Temple, London, and within the parish of the blessed Mary at Strand, then called the Savoy, in his county of Middlesex (the liberty and duchy of Lancaster excepted, and always reserved)." This constitutes the present extent of the city and liberties of Westminster.

The creation of St. Martin's parish, being an occurrence connected with the large addition of nearly 900 acres in the manor of Eia to the franchise of Westminster, is a subject intimately connected with the situation and extent of Westminster.

The parish of St. Margaret constituted the whole of Westminster in 1222, the manor of Eia not then forming any part of that parish. For creating the parish of St. Martin in the Fields, the larger portion of what had constituted the parish of St. Margaret was abstracted from it, thus contracting the northern limit of St. Margaret's to a line passing through the present ornamental water of St. James's Park to the Tyburne in its passage towards Tothill Fields. On the west side of Tothill Fields, the Tyburne watercourse passed from the Tyburne Road (now Oxford Street), and was in the whole of that length the boundary of the ancient parish of St. Margaret.

Maitland observes that the constitution of St. Martin's parish, as well as the foundation of its church, is involved in uncertainty. The church, with a cemetery, is mentioned only as such in the decree of 1222. This must therefore have been, according to a custom of that period, a church for the convenience of administering divine service to the neighbouring inhabitants, without any parochial endowment being attached to it.

In documents which were produced at a trial in the Court of King's Bench in the Hilary term of 1828, "Fenn against Golding and other Churchwardens of St. Martin's in the Fields," lands are described so early as the year 1225 as being in the parish of St. Martin of Charing, and afterwards others appear described as being in the parish of St. Martin in the Fields. It does not, however, seem to have been a confirmed parish until some time after 1306, which is the first date of the registry of the diocese of London. Newcourt, who was principal registrar of that diocese for nearly twenty-seven years, represents the registry not to be defective from its commencement in 1306 to the year 1337, but that no registry existed from the latter date until the year 1361, when it again appeared without being defective for the space of fourteen years. He states from this registry that in 1363 (fifty-seven years after its commencement) Johannes . . . was instituted vicar of St. Martin's parish on the resignation of Thomas Skyn. Skyn may have been the first or a succeeding vicar; but as neither his institution nor that of any previous person appears in the existing registries, the first institution of a vicar, originating with the regular constitution of the parish, must be concluded to have taken place during the period of the deficient registry, about twenty-three years between 1337 and 1361.

Widmore notices a dispute "concerning the right to visit the hospital of St. James," and states that "in June, 1342, a trial came on, and the jury gave a full verdict for the Abbot, inasmuch as it was within the parish of St. Margaret." This decision makes it appear that St. Martin's was not then so far a legalised parish as to take from these parts the parochial rights of St. Margaret's, thus reducing the period within which St. Martin's became a regularly constituted parish to about nineteen years, between 1342 and 1361.

It seems by the order of 1345 for inquiring of lands which were of Edmond Barber "in Eye," that this manor was not then an acknowledged part of Westminster; which is presumptive evidence (grounded on the belief that the lands "in Eye" were comprised in the parish of St. Martin when its confirmation took place, and as such became included within the franchise of Westminster) that St. Martin's was not an ordained parish until after 1345; thus again reducing the period within which it occurred to about sixteen years, between 1345 and 1361.

The last interval brings the time very near to the period at which Westminster became a considerable commercial mart by the attainment of the wool staple, which must have greatly added to its already increasing importance, consequent on the king's residence, and on the more permanent establishment there of the Parliament and the courts of law. These circumstances, added to the purpose of concentrating its newly

acquired privileges, might have suggested the design of giving this locality a distinct character, and by a regular constitution of St. Martin's parish, of contracting that of St. Margaret to the limit of the intended town of Westminster. The wool staple was fixed at Westminster by the Act 27 Edward III., s. 2, cap. 1; and it is probable the establishment of St. Martin's parish took place during the eight years between 1353, the date of that Act, and the reappearance of the registry of the diocese in 1361.

In Richard II.'s charter of 1393 the parish of St. Margaret is merely described as the town of Westminster, and the parish of St. Martin in the Fields is, with others on the eastern border of the same, declared to be wholly within the franchise of Westminster.

Still the precise line of division between the two parishes of St. Margaret and St. Martin, as well as what strictly constituted St. Martin's parish, does not seem to have been settled before the time of King Henry VIII. This may be attributed to an endeavour on the part of the monastery to have their various lands and other premises, which lay within the assumed circuit of St. Martin's parish, continued parcels of St. Margaret's parish, as they had been before the division took place. The following particulars throw considerable light on the subject.

The deed by which possession of Whitehall was given to the king is dated February 12, 21 Henry VIII. (1530), being a record in the Exchequer endorsed "York Place, Middlesex—a Recovery by Cardinal Wolsey."

September 5, 23 Henry VIII. (1531), is the date of a surrender by the Abbot and convent of Westminster among other premises of the lands which afterwards formed St. James's Park, described to be lying on the south side of the highway leading from Charing Cross to the hospital of St. James, and from the aforesaid hospital on the south side of the highway extending towards the west to the cross called Eycross.

In a letter of November 11, 26 Henry VIII. (1534) to the Abbot of Westminster the king says, "Our manor at Westminster ys nowe scite and sytuat as in the myddes of two p'shes. That ys to saye of Saynt Margaret where ye have jurydixon ordinary, and of Saynt Martyn in the Felde whe' ye be poss'ion's and prop'etaries." And in a letter of February 16, 26 Henry VIII. (1535) to the vicar of St. Martin's parish, the king directs that the inhabitants "dwelling from the Newgate of our manor of Westmynster shall be from hensforth taken for pyshoners of St. Martyn's, and there to here there devyne s'vice."

The Act 28 Henry VIII. cap. 12 (1536), declaring the limits of the king's palace at Westminster, states that the king "thereunto adjoining hath made a park walled and environed with brick and stone." And, in reference to the same in a patent dated March 21, in the thirty-third year of his reign (1542), the king, "in recompence of the Tythes, and other ecclesiastical rights, which the parish church of St. Martin's in the Fields, Charing Cross, in the diocese of Westminster, hath for ever lost by the imparking of certain farms and other titheable places situate in the parish of the same church," grants and ordains that all titheable places till then continued as parcels of the parish of St. Margaret, and being between the parish church of St. Clement without Temple Bar and the Palace of Westminster, together with the inhabitants thereof, should thenceforth be deemed to be of and in the parish of the said church of St. Martin's in the Fields.

By the following statement it appears that a considerable portion of the land which afterwards became St. James's Park was, prior to this change, within the parish of St. Martin, and there being an inconvenient intermixture of that and the adjoining parish of St. Margaret, within the king's manor of Westminster, directions are given that thenceforth the parish of St. Martin should be taken from the new gate of that manor. Sir Christopher Wren considered the King Street gate to be the new gate spoken of in the king's letter to the vicar of St. Martin's, but the style of that building denotes it of a later period than the date of the letter. In examining Fisher's plan of Whitehall Palace from a survey in 1680, there can be little doubt that the present parish boundary, commencing at Whitehall Stairs, situated as formerly by the river side, corresponds with a line that would pass through the principal entrance of the palace, as shown in that plan, and this very well accords with a conventional boundary running from the east in a straight line along the park to the Tyburne stream (at that time called the Eye) west of the park.

The Act of 28 Henry VIII. cap. 49, shows that the three manors of Nete, Eybury and Hyde, which had constituted the ancient manor of Eia, were in 1536 acknowledged parts of Westminster. They were probably made part of St. Martin's when it was regularly ordained a parish, prior to 1361; but the circumstance of their not having then been deemed to be within the franchise of Westminster may account for seeking Richard II.'s charter of 1393 to declare St. Martin's parish to be wholly included within that franchise. The

manors continued to form part of St. Martin's parish until they were constituted the separate parish of St. George, Hanover Square, in 1725, with a very small change in the eastern border of the Eybury manor, the parish of St. George being the last of the four abstracted from the parish of St. Martin since the restoration of Charles II. in 1660.

DRAWING FOR PROCESS REPRODUCTION.*

(Concluded from last week.)

ALTHOUGH for special decorative reasons, such as the Birmingham school rank so highly, it is quite possible to imitate a Dürer woodcut so as to deceive the very elect, there seems no particular virtue in so doing. Still if this be the object, it would be quite legitimate to draw it in white upon black paper, as indeed several artists of this school do. Such a method, they say, is more akin to hewing out the whites on a wood-block. This may seem a fanciful explanation, the truer one being that if you are working in this way you can hardly help simplifying your forms and endeavouring to get as much effect as possible with comparatively few touches. For this reason working in white upon a darkened ground is likely to keep the designer more near the spirit of the archaic school he desires to imitate.

Yet it is but fair to say that the one school of English art (since Constable) which has provoked the sincerest flattery of imitation from continental artists is the so-called pre-Raphaelite school, which in all its different manifestations, from Rossetti to Miss Kate Greenaway, from Blake and Mr. Walter Crane to the Birmingham school and Mr. Aubrey Beardsley, has already influenced French and German contemporary art to a considerable extent, while modern Holland and Belgium are entirely fascinated by its methods.

We are told that this decorative line is the only one that will accord with type, and stand in due relation as part of a perfect page. Granting this claim to the utmost, it seems to me you have only granted that a certain form of page has realised one perfect ideal of symmetry and proportion, which precedent has established as satisfying our taste completely. But that this ideal is the only one, and that beauty may not be sought in connection with any other page of type, with fine woodcuts, or even the much abused half-tone, is quite another question. Because many of us delight in the older ideal, and are quite willing to endorse all that can be said in its praise, I fear we are weak enough to allow all other ideals to be tacitly forbidden. It seems to me that if only an artist of authority would defend the modern page at its best, and point out where the type and illustrations at present failed to harmonise, and would analyse the question of vignettised as opposed to framed illustrations; would decide whether the rigid rectangle of the drawing with a set outline was or was not more pleasant in connection with the whole page than a vaguely softened outline straying, maybe, into the margin; and, above all, would try to formulate the most pleasant proportion of the face of the type to the illustrations, something might be done to establish a new ideal. Possibly, as the heavy line of the old woodcut accorded with the heavy and beautiful type of the period, so now with a more delicate scheme of illustration, relying upon the values of masses rather than upon lines, whether produced by fine woodcut engraving or the half-tone process, we must endeavour to use a lighter-faced type, perhaps more closely set together, to gain a silvery mass of grey rather than parallel lines of dark grey with vivid white lines separating them, which is the effect of the average page of type to-day.

For the art of drawing for process reproduction should, I think, find the artist keenly alive to the final presentation of his work. It seems a most desirable thing that he should be interested far beyond the receipt of a cheque from the publisher. Indeed, the future of illustration is only hopeful if we look forward to the co-operation of artist and art editor or publisher in a way undreamed of in the past.

It should be deemed absurd for a publisher to order so many drawings of a certain size without telling the artist the style of the book they are intended for. Or if they be destined for a periodical which more or less keeps a permanent standard of arrangement, then the artist should know before if he is to fill a whole page or half or quarter, as the case may be. He should know the type to be employed, the surface of the paper and the colour of the ink. If half-tone is to be used, he should be consulted on the reduction of his drawing, whether a coarse or fine grain is to be used, and, above all, in work of any pretension he should be allowed to select a decent firm of engravers, and to be assured that printers who understand the delicacy of the half-tone block are ultimately to be responsible for the production.

The mere mention of the printer is touching upon the most sore point of all, because there can be no doubt that he is at present the drag on the whole machinery. Good drawings are to be had, good blocks are to be obtained—but good printing in the modern style is, if not unknown, at least rare.

How far this is due to the ink, to the varying temperature of our offices, which are rarely heated thoroughly, is not easy to settle. Practical printers in America with whom I have discussed the subject frequently, generally attributed our non-success to one of these two reasons. Mr. De Vinne—as I said before—went further into the matter, and attacked our paper, ink, and above all our custom of using a yielding instead of a solid bed. He acknowledges that for such book printing as the Chiswick Press has turned out for so many years, England was still easily first.

When editor of an American magazine, it was my duty once a month to go down to the printer's and there, in the office itself, to see the pages upon the press, to look over the locked formes and suggest slight changes in position of the blocks, or alteration in their titling, and so to make a final attempt to bring the whole page into that symmetrical condition which defies all rules and can only be done by instinct. I wondered how much of the unsatisfactory state of English printing was owing to the separation of the various departments in publishing a book or periodical, which should be under one control. If the paper itself is ordered by one member of a firm, the blocks by another, while a third is responsible for passing the sheets, and the printer is allowed his choice of ink, his own disposition of the blocks—in fact, to put the impress of his taste on the work—can we be surprised that the result is not homogeneous? One mind should be apparent through a book or periodical. If it could be the artist, it would be ideally the best; but a number of artists must needs be employed on a single volume in certain cases, and as their time is too valuable to be spent on practical details outside their craft, even if one granted their agreement in these matters, there must needs be an actual art editor—not merely one nominally so-called, but a man fairly conversant with all those questions involved—one who could be trusted to consider every one of the thousand-and-one items which go to build up a beautiful book. The binding, the end papers, title-page to colophon, arrangement of blocks, every detail small or great—all should be in accordance with one standard of taste. If such a one were wise he would keep himself in touch with the artists who worked with him, and by informal conferences let them know beforehand such matters as would affect their drawings, and in turn obey their wishes as to the reduction of drawings, the placing them in the page and the style of titles to be printed underneath, and all these trifles which make or mar perfection; and, on the other hand, he should work in equally intimate relation with his printers and be a constant visitor to the machine-room, supervising all.

This may seem a side issue to introduce into drawing for process, but it is in ways like these that half the mischief lurks to-day. What is everybody's business is nobody's business; you may as well expect a firm to write a sonnet, as its members, acting independently, to produce a perfect book. One could name not a few magazines where money is apparently freely expended—where capable artists, good process engravers and adequate printing unite to produce a chaotic medley that seems to have no method in its muddle. On one page you see an idea of balance and a sense of "colour" in the disposition of type and process blocks, in the next the office-boy was apparently left to stick the pictures anywhere on the page and the printer told to fill up the rest with type. Of the constant intrusion of the photograph from life with all its unselected mass of detail, among reproductions of drawings, much might be said. The awful examples of certain American magazines that have illustrated fiction by photographs of posed models is only one step more in the direction of artistic depravity. For views, passing events and a score of other subjects the photograph is most welcome; but when it is set in rivalry to the artist even the most tolerant must protest. We object to an undue use of the costume model in paintings, but at its worst the custom is praiseworthy compared with the figure posed by way of illustrating poems or stories. In such a practice is surely the nemesis of ultra-realistic art—the realism that defeats its own end and becomes more hideously conventional than the worst efforts of romance.

Photogravure is too far removed from the subject to be more than touched upon here; the almost universal preference shown by artists for their pictures to be reproduced by this method in place of steel or copper engraving, mezzotint or etching, is sufficient to urge in its defence were any needed. In more sumptuous editions of late years it has been employed for the reproduction of wash drawings, but the result in many cases is not so far in advance of a good half-tone that it warrants the large increase of cost. For reproductions of engravings, pencil drawings and the like, it may be fairly claimed to be absolutely the best mechanical process.

Colour printing by process blocks is obviously upon us. Of the curious achievements wherein the colours are dissected

* A paper read by Mr. Gleeson White on February 5 at the Society of Arts, in the Applied Art Section.

by mechanical agency and the resultant negatives made into blocks and superimposed in three or more primary pigments, so as to yield a naturalistic effect of colour, silence is the kindest criticism. As scientific experiments they are most interesting; as commercial products they are very promising; but so far as art is concerned, the worst chromo is preferable so far, although there are not wanting signs of better things, such, for instance, as a reproduction of a water-colour sketch, given with the February *Artist*, reproduced by Messrs. Hare's process. Possibly, for patterns and reproductions of coloured drawings made with a view to their special requirements, they will become widely and not undeservedly popular. Then it will be necessary in any chat upon drawing for process to give a series of hints on the best pigments and their rightful limitation—for making originals to be reproduced in this way. But if we look around and see what has been done by woodcut printing in colours in the past, the Walter Crane toy books, or those wonderful Japanese prints which are an endless source of delight to Western minds, a hopeful future unfolds. Possibly the gradation of tint, which is the charm of much Japanese work, can never be hoped for from machine printing; it is the work of the artist craftsman, not of the machine, however deftly guided. Stippling is a poor substitute, and superimposed colours, except for bold work, like posters, has a peculiarly unpleasant effect.

If, however, we boldly accept the mosaic of solid colours, with or without those black separating outlines which govern a large mass of Japanese prints, and seem to be equally applicable to the decorative school of English art, it suggests a possible method that might even take its place among the ordinary commercial products of the day and yield excellent art. But for such printing as the earlier Walter Crane toy books, it seems to me that hardly anything has yet been attempted by process blocks. If we are intent to avoid superimposed colours and to be chary of stippled and mechanically-produced shades, good effects might be realised even by machine printing and cheap process blocks.

Like it or not, cheap and rapid colour printing is upon us. Paris has already its daily papers illustrated in colours. Regarded independently as a specimen of typography, this journal may not escape criticism. But when you consider that 6,000 copies an hour are struck off from a rotary press and 40,000 issued daily, it is astounding. The particular rotary machine which accomplishes this result is being duplicated for London, and I am breaking no secret in saying that by its aid popular colour printing in ways hitherto undreamed of will shortly assume a prominent place in journalism.

A modification of colour which consists roughly of two half-tones—the one prepared for the contours, the other for the modelling—has much to recommend it, especially for the reproduction of oil-paintings; so far the ideal seems to have been to imitate a colotype. Sometimes, as in a reproduction of a picture by Mr. Waterhouse in *The Studio* for January, a very fair rivalry results. Now a colotype—I speak after Mr. Frederic Hollyer, whose opinion is entitled to peculiar respect in such matters—is perhaps the best of all reproductions by mechanical means; that is to say, the next best thing to a good platinotype or a silver print. But it is far more costly and demands more time for its production. The advantage of this half-tone method is that it can be worked in conjunction with typography, not necessarily even on separate sheets. Therefore, this half-tone, printed in two shades, may have a not dishonourable future before it. And in the reproduction of paintings, indeed, if the artist properly understood its limits, there may be possibilities in it which would give to the half-tone more vigour and more atmosphere, and fit it for the illustration of modern books where high finish is demanded.

It has seemed unnecessary to refer to the triumphs of native process work, some examples of which, by the courtesy of various firms, are on the walls to-night. But a little time ago it was almost essential to send work abroad because of the unequal level of British blocks. Now there are several firms who can rival the best French or Austrian work, and each day sees a higher average in the better class work all round.

There is another question outside my text, as indeed most of this rambling discourse has proved to be, which should be taken up in earnest by some society of importance. I mean the preservation of the originals of the drawings produced literally by hundreds every week for our periodical publications. Some day we shall regret the carelessness which has already allowed so many to vanish no one knows where. Some few firms indeed sell now and again such pictures as have a certain independent interest of their own. But in almost every office of London at the present day piles of drawings are accumulating, some of which we have a right to expect will be not without interest to future generations. Who would not prize the originals of thousands of woodcuts of the days before photography, when the drawing perished in the cutting? Now this does not happen. Before it is too late one may hope that a number of contemporary drawings may be

rescued and preserved in some museum or gallery for future reference.

We must not, however, ask too much of contemporary periodical literature; not every fifteenth-century book is a masterpiece, not every etching, old or new, is a Rembrandt or a Whistler. If one in a thousand—one might say one in ten thousand—illustrations to-day find its future immortality in these ephemeral publications, we shall have a fair number to justify the existence of the rest. Nature is careless of a million failures so one survives, and art need not be expected to be more fecund.

Personally, it seems to me that the present period is for illustration what the Elizabethan was for lyrical poetry. There in a hundred books of airs you find words of songs any one of which might make the reputation of a poet to-day. So it may be that Mr. Pennell's anthology of pen draughtsmen will be to future students what "Tottel's Miscellany" or Mr. Bullen's charming anthologies are to students of poetry, priceless collections of the work of artists, many of whom would have been absolutely unknown but for this preservation of their ephemeral work.

Possibly this period will stand out not as the age of fresco, or the age of oil or water-colour pictures, but as the age of black and white illustration, which, for the most part done without thought of immortality, gained it unawares.

GREEK STUDIES.*

By P. MORLEY-HORDER.

AN architect's library can easily, nowadays, be usefully extensive, but if it merely consist of handbooks and illustrated and tabulated examples of fine buildings, it will be sadly uninspiring and incomplete—a reference library for personal convenience at most. In short, we want among our books, besides the usefully topographical, so to speak, the æsthetically suggestive. Such a book, for instance, as Fergusson's "History of Architecture" defines for us the various stages of our art; it is the geography of the subject—an attempt to set forth without bias the development of architecture from the earliest ages. Inspiring or interesting it almost ceases to be from very usefulness, and had it been either, and possessed of the fine flavour of literature, its reliability might possibly have been seriously impaired. For who could write with enthusiasm of the art of each age? Here, then, is a work invaluable for our information and the groundwork for our personal intuitions and impressions. The exact relative perspective of each style must, too, be exaggerated in a work of this dimension, when we consider how insidious is the connection that binds each smallest stage in the history of architecture. What we want more is that literary art which will make each age live more really for us, which will give us the *résumé* of the spirit that led up to each change and the very atmosphere that encouraged it. If the text-book tells quite accurately and indisputably how one style merged into another, it may do this to small purpose unless we at the same time instinctively feel this—unless the cumbersome facts are bound up together with a fine cord of consequence. This, as I have said, requires the artist imbued with the real spirit of the times, who from very affection consciously understands each tendency of the age he writes about. Such a writer as Ruskin, for instance, however bigoted and unreliable at times, can nevertheless tell us more about the essentials of the Gothic spirit when describing a small detail of one of its examples than all the text-books. Such books are a constant relaxation, and help us to realise and be reminded that our buildings have an informing spirit attributable to all sorts of external agencies—that they are not mere blocks of material. In fact, all literature that illuminates the past must necessarily throw light on the arts, and as being in itself but another branch of art should be cultivated for its own and refining influence sake. "Examine" is the cry everywhere, and just at present particularly so in the architectural world; and as it is impossible to reduce this instinctive knowledge of the real feeling of each age towards the arts altogether to paper, the tendency to be satisfied with this text-book knowledge is emphasised. Now, it is quite possible to have a very true feeling for this indefinable distinction of style unaccompanied with a sufficient knowledge of mere data to satisfy an examiner. With a very accurate knowledge of the characteristics of each style we may yet lack that larger interior knowledge no text-book can give. Important and essential as this exact knowledge is, it is lifeless and unprofitable without the vivifying freshness of the literary touch of the great writer.

The book before us seems an instance of real inspiring knowledge in the treatment of a particular art, and seems altogether a helpful book in the way I have tried to set forth. To turn for a moment from the book to the gifted

* *Greek Studies*. By Walter Pater. (London: Macmillan.)

author, whose death seems all the more untimely when we are told in the preface that the paper on Greek sculpture would have grown into a series, including one or more essays on Phidias and the Parthenon. The book as it stands is chiefly made up of essays that have appeared from time to time, but gathered collectively and forming the last volume of a series of critical art studies of priceless worth. Mr. Shadwell, in an admirably brief preface, emphasises, what an acquaintance with Mr. Pater's volumes so amply sets forth, that their merit cannot be summed up by describing them as consummate specimens of style. He points out, that his distinction does not lie in literary grace, fastidious choice of language and power of word painting alone, but in the depth and seriousness of his studies. The delicacy of insight and subtleness of interpretation, which with him seem an instinct, are the outcome of hard, patient, conscientious study.

The last three essays will perhaps seem of greater interest to readers of this paper, but all of them should tend to enlarge our ideas of that old Greek world which seems under his influence to grow less pagan, more full of human interest, and nearer than we ever could conceive to modern civilisation. The mythical elements were of greater import to the Greek mind than we perhaps thought; in fact, they become, when rightly studied, less mythical and more the expressive avenues of utterance for an imaginative people. We dare not question Mr. Pater's interpretation of these myths, so fascinating and consequential seems each chain of thought. Dionysus—perhaps to most of us only the vine-clad god—is indeed a god of larger meaning, the exponent of countless human feelings. "Yearly about the time of the shortest day, just as the light begins to decrease, and while hope is still tremulously strung, the priestesses of Dionysus were wont to assemble with many lights at his shrine, and there, with songs and dances, awake the new-born child after his wintry sleep, waving in a sacred cradle, like the great basket used for winnowing corn, a symbolical infant, or perhaps a real infant. He is twofold then—a Doppelgänger—like Persephone; he belongs to two worlds and has much in common with her, and a full share of those dark possibilities which, even apart from the story of her rape, belong to her. He is a Chthonian god, and like all the children of the earth has an element of sadness; like Hades himself, he is hollow and devouring, an eater of man's flesh—sarcophagus—the grave which consumed unaware the ivory-white shoulder of Pelops."

In this first essay we have, in Mr. Pater's own words, "an endeavour to present, with something of the concrete character of a picture, Dionysus, the old Greek god, as we may discern him through a multitude of stray hints in art and poetry and religious custom, through modern speculation on the tendencies of early thought, through traits and touches in our own actual states of mind, which may seem sympathetic with those tendencies."

The second essay deals with the Bacchanals of Euripides—"an example of the figurative or imaginative power of poetry, selecting and combining, at will, from that mixed, floating mass, weaving the many-coloured threads together, blending the various phases of legend—all the light and shade of the subject—into a shape, substantial and firmly set, through which a mere fluctuating tradition might retain a permanent place in men's imaginations."

A rather long but interesting quotation from the essay on the myth of Demeter and Persephone will best give some idea of the way Mr. Pater explains the gradual growths of these myths until they became an essential part of all Greek art and life. Based on no historical facts, but arising out of the natural spirit of man, and embodying symbolically his deepest thoughts concerning the physical and spiritual life, these myths have influenced all ages, and may still exercise a solemnising power over the modern mind—they may still exist for us and purify our culture.

"In the story of Demeter, as in all Greek myths, we may trace the action of three different influences, which have moulded it with varying effects, in three successive phases of its development. There is first its half-conscious, instinctive or mystical phase, in which, under the form of an unwritten legend, living from mouth to mouth, and with details changing as it passes from place to place, there lie certain primitive impressions of the phenomena of the natural world. We may trace it next in its conscious, poetical or literary phase, in which the poets become the depositaries of the vague instinctive product of the popular imagination, and handle it with a purely literary interest, fixing its outlines or simplifying or developing its situations. Thirdly, the myth passes into its ethical phase, in which the persons and the incidents of the poetical narrative are realised as abstract symbols, because intensely characteristic examples of moral or spiritual conditions."

Space will not allow of my quoting the application of this sequent evolution of myth to that of Demeter and Persephone, full of interest as it is. The Homeric hymn is the central expression of the literary grace and poetical phase of Greek mythology, whilst the marble remains, with which Mr. Pater deals in a later essay, are the central extant expression of what he describes as the ethical phase.

The "Heroic Age of Greek Art" has been imaged wrongly; it has too often been regarded as cold and lifeless. Mr. Pater finds the circumstance "that Greek sculpture is presented to us in such falsifying isolation from the work of the weaver, the carpenter and the goldsmith, an encouragement to such a manner of regarding it." Within the grey walls of the Louvre or the British Museum, "isolated from clear Greek skies," it is not surprising if the more sensuous aspect has been forgotten. Again, Mr. Pater reminds us that nothing remains, on account of the perishableness of their material, of "the curious woodwork, the carved ivory, the embroidery—coloured stuffs on which the Greeks set much store—of that whole system of refined artisanship, diffused like a general atmosphere of beauty and richness around the more exalted creations of Greek sculpture." A real conception of Greek sculpture cannot be formed without on the one hand connecting it with the "inner life of the Greek world, its thought and sentiment; on the other hand with the minor works of price—intaglios, coins, vases; with that whole system of material refinement and beauty in the outer Greek life which these minor works represent to us. It is with these, as far as possible, that we must seek to relieve the air of our galleries and museums of their too intellectual greyness. Greek sculpture could not have been precisely a cold thing, and whatever a colour-blind school may say, pure thoughts have their coldness, a coldness which has sometimes repelled from Greek sculpture, with its unexpected fund of passion and energy in material form, those who cared much and with much insight for a similar passion and energy in the coloured world of Italian painting."

GENERAL.

The Surveyors' Institution meets on Monday, the 4th inst., when the adjourned discussion on the paper read by Mr. Arthur C. Pain, C.E., on "Light Railways" will be resumed.

At the Students' Meeting of the Institution of Civil Engineers on Friday evening, the 8th inst., Mr. A. Struben will read a paper on "The Co-ordinate System of Surveying as employed in South Africa."

Mr. Walter Hanstock, of Batley, has been instructed by the Dewsbury Board of Guardians to prepare plans for alterations at the old infirmary.

Canon Egerton, at the annual meeting of the Shropshire Archaeological Society, read an interesting descriptive and historical paper on "The Parish of Middle," in which he stated that there are in the church three chained books of over 300 years old. He also showed an ancient seal and ring, which have recently been dug up in the parish.

The Commissioners of the Board of Manufactures have appointed Mr. Robert Gibb, R.S.A., to the vacant office of Principal Curator and Keeper of the National Gallery of Scotland, subject to the approval of the Government.

The Prescot Guardians have decided to order plans for the erection of a new infirmary at Whiston, at a cost of 35,000*l*.

Mr. R. G. Rice, F.S.A., will read a paper entitled "Notes on Huntington Shaw, blacksmith: his reputed work; his tomb, formerly at Hampton, Middlesex, and ironwork from the railing of the same," at the meeting of the Royal Archaeological Institute of Great Britain and Ireland on Wednesday, the 6th inst.

Mr. A. Hunter Crawford will read a paper, "The Suburban House," at the meeting of the Edinburgh Architectural Association on the 6th inst.

Mr. W. C. Howden, at the meeting of the Northern Architectural Association, read a paper on "Organs and Organ Chambers."

At a Meeting at the Mansion House, on Friday, of the committee formed to provide a suitable memorial of the late Field-Marshal Lord Strathnairn (Sir Hugh Rose), at which the Duke of Grafton presided, it was reported that the bronze equestrian statue by Mr. Onslow Ford, A.R.A., was now being cast, and, with its pedestal of Portland stone, would be in position at the selected site at Knightsbridge, at the junction of Sloane Street, by April 30.

A Private View of the Spring Exhibition of Pictures will take place at the Atkinson Art Gallery, Southport, to-day (Friday).

Professor H. G. Seeley, F.R.S., will this season give his annual course of lectures, in connection with the London Geological Field Class, at Wortley Hall, Seven Sisters Road, N. (adjoining Finsbury Park railway station), on the four Thursdays in March, commencing at eight o'clock—Subject: "The Nature and Forms of Hills and Valleys." Further particulars can be obtained from the general secretary, Mr. R. Herbert Bentley, 31 Adolphus Road, Brownswood Park, N.

The Architect.

THE WEEK.

THE quinquennial revaluation of property in the Metropolis is about to take place, and the finance committee of the London School Board are making arrangements in view of the appeals which may have to be made against the assessments of schools. The Court of Assessment Sessions in 1886 decided that the Board were to be considered hypothetical tenants, and that the cost of purchasing the land for erection of the schools was an element which might fairly be taken into consideration in assessing the schools, and further, that $3\frac{1}{2}$ per cent. on the value of the land and $4\frac{1}{2}$ per cent. on the cost of the buildings were fair percentages for ascertaining the rateable values. But recently a Conference on assessment procedure and practice was held, at the invitation of the London County Council, by representatives of the metropolitan assessment authorities, when resolutions setting forth the methods of computation which should be used throughout the Metropolis for fixing the assessments of various classes of properties were adopted. One of them was the following:—"Public buildings (including work-houses, vestry-halls, public libraries, schools, baths, wash-houses and hospitals) should be assessed at a gross value calculated at 4 per cent. on the present value of the land and 5 per cent. on the value of the buildings erected thereon." The percentages named in the resolution produce an assessment which is somewhat lower than that obtained from the Board's percentages of $3\frac{1}{2}$ on the value of the land and $4\frac{1}{2}$ on the value of the buildings for arriving at the rateable value. For instance, assuming the value of the land to be 1,000*l.* and the value of the buildings to be 1,000*l.*, then the assessment obtained from the Board's percentages would be 96*l.* gross value and 80*l.* rateable value, whereas from the percentages named in the Conference resolution, it would amount to only 90*l.* gross value and 75*l.* rateable value. As the representatives at the Conference possessed special knowledge of assessment matters in the Metropolis, the financial committee of the School Board are of opinion that the above resolution of the Conference may now be taken as a basis for the assessment of the Board's schools.

So few clergymen now take interest in the remains of Mediæval architecture in England, the death of Canon VENABLES on Tuesday is a loss to the country. He was in his seventy-sixth year. As late as February 17 he delivered a lecture in Toynbee Hall on Lincoln Cathedral, which in his eyes was a building of surpassing interest. Canon VENABLES was a zealous clergyman, and his ecclesiastical duties were never sacrificed to his hobby. We have published many of the papers he read on architectural and archæological subjects, especially those of the Lincoln district, which were all marked by as exact a knowledge of architecture as could be expected in an amateur; as well as sound judgment in drawing conclusions.

If, as is likely, the insuring of the safety of the Parthenon and other temples on the Acropolis will require costly works, the Greek Government will be justified in appealing to Europe and America for assistance. Athens has a claim on all civilised countries, which is not likely to be denied. But with international support there should be international supervision. The German architects who have succeeded in gaining a monopoly of responsibility are excellent men, but we see no reason why Frenchmen, Italians, Englishmen and Americans should not also be consulted on so important an undertaking as the upholding of the temples. Nor would the summoning of other aid add much to the expense. There are architects in England, as elsewhere, who would be proud to render honorary services. The Greek Government may be unable to act with the freedom that is desirable at such a juncture, but hitherto the partiality exhibited does not promise to lead to a successful consummation of the project.

THE forthcoming Berlin Exhibition has created a new subject for contention among the French painters. The question is again asked whether a Frenchman can send a picture to the Moabit Galleries without sacrificing his patriotism? As was to be expected, the Society of the Champs-Élysées has taken a different view from the Society in the Champ de Mars. The latter, in the person of the president, M. PUVIS DE CHAVANNES, says if there is to be war between the two countries let it be undertaken, but as long as Frenchmen prefer to live in peace, why should they not act towards the Germans as they desire the Germans to act towards them? It is supposed that the International Exhibition of 1900 will have a German section, and that will impose far more sacrifice than the sending of a few pictures to Berlin. Although it is delicately screened, the question is one of finance. The German amateurs will not purchase French pictures, and it is therefore waste of labour to display examples in Berlin. The older Society has had experience enough of the futility of foreign exhibitions, and accordingly hesitates about renewing the risks of taking part in any of them. In the Society over which M. PUVIS DE CHAVANNES presides there are younger men and creators of new styles. They are imaginative enough to suppose that the sight of their pictures in Germany will create converts to their innovations.

THE Emperor of GERMANY has determined on another attempt at the restoration of an antique statue. In the Old Museum is a *Dancing Mænad* or *Bacchante*, which is imperfect. The Emperor offers a prize of 2,000 marks, or 100*l.*, for a restoration of it. Every German artist is eligible to take part in the competition. All of them who care to make a trial can obtain a carefully produced cast of the figure for 30 marks. The result of the competition will be determined on January 27, 1896. The last attempt was made on an antique head, but the *Dancing Mænad* is a more ambitious work, and will therefore need finer skill to be properly restored. The exercise will be beneficial, for only in that way can the inimitable character of Greek work be realised. The Renaissance sculptors who restored so many antique figures were rarely successful, but the world has grown accustomed to their additions, and the incongruity is therefore less painful than it should be considered.

THE repetition of fires in Toronto was among the subjects considered at the late Congress of the Ontario Association of Architects. The following precautions were recommended:—"First, as great care as possible to be taken by isolation from the surrounding buildings either in space or by effective outside walls. Second, the introduction by the Corporation of Toronto of the London (England) Building Acts as to brick walls and other building appliances now in operation in the largest city in the world. Third, great care in the selection, as far as possible, of indestructible materials, and such as will stand the action of great heat and steam. Fourth, greater introduction of hydrants into any newly erected buildings. Fifth, careful general supervision. Sixth, special care in the heating and ventilation. Seventh, introduction of new methods by the architectural profession, such as automatic apparatus, &c."

EXCAVATIONS are about to be undertaken on the Hill of Tara by the British Archæological Association, with other supporters, under the direction of Mr. GEORGE PAYNE, the hon. secretary of the Kent Archæological Association. It is not anticipated that the Tara Halls, over which so many poets have rhapsodised, will be revealed. They consisted of enclosures of earth or mud, for the halls were open to the heavens. What is sought is simply the tomb of TEA TEPHI, a princess who is the subject of many legends. According to tradition, she was an Egyptian princess who found her way to Ireland, where she captivated HERMON, one of the numerous kings, who settled Tara upon her. It is proposed to excavate for a depth of 14 feet, and if nothing is discovered to sink shafts in other places. If the tomb is not revealed, something else may be met with to reward the archæologists. But as the princess has been mouldering for ages, her dust ought now to be considered sacred and left undisturbed.

PROFESSOR BLACKIE.

THE majority of the criticisms on the late Professor JOHN STUART BLACKIE which we have read have hardly done justice to a very remarkable man. He never seemed to grow old. Until his last days his figure was erect, his step elastic, his eyes as bright as if he had not reached his half-century. With so much vitality it is no wonder he felt as a young man, and attempted many things in a manner which shocked the lean and slippered pantaloon who had not reached his great age. They declared him to be eccentric, shallow and vain. As opinions of an uncharitable kind are sure to spread, it was gradually concluded that Professor BLACKIE was always eccentric, and his numerous writings were supposed to have originated in that quality.

There is no doubt that JOHN STUART BLACKIE was unlike the majority of professors. It was his business to teach, but if he lived to the age of the patriarchs he could never become a "book in breeches." At one time in England a schoolmaster who wrote a volume on the Greek particles was sure of a bishopric. BLACKIE would say there never was a Greek who occupied himself with a subject of that kind, and a scholar who devoted himself to it was less adapted to rule clerics and laymen than an old Athenian. The dead letter of literature was to him like dead things of other kinds—that is, to be avoided. Dr. JOHNSON considered the Greeks must have been as ignorant as Mr. THRALE's draymen, because they did not possess books. Professor BLACKIE, on the other hand, believed there was a better education to be obtained in the public places of Athens than in any of the Scottish or English universities. Knowledge that was embalmed in books appeared to him to be inferior to the words and acts of living men. Hence it was he startled scholastic proprieties by advocating that students of HOMER and ARISTOPHANES should spend a part of their time in Athens, for although they could not hear the winged phrases of the ancients, yet the talk in the streets of the city was preferable to any commentator's dissertation. Hence it was also that when he translated the "Iliad" he adopted ballad metre, for he felt that neither "Evangeline" nor the "Bothie of Tober-na-Vuolich," nor the numerous other experiments, can make the old heroic measure have the influence over the British mind which is desirable if the lines of the epic are ever to become household words. The old minstrels and SCOTT have made us associate the ballad with feats of broil and battle like those which HOMER describes, while such prosody as was adopted by POPE can never be identified with anything but moral essays. Professor BLACKIE probably felt he was never so vigorously preparing himself for his attempt on the "Iliad" as when he was learning the songs of German *burschen* and translating them in such a way that the English words could be used with the approved melodies.

It would be strange if a man who endeavoured to study and express Greek literature as if it were a vivid actuality should be neglectful of art. Generations of professors and scholiasts contrived to do so in all the colleges of Europe, but the reason was that Greek was accepted as no more than a collection of printed and written words, which for scholastic purposes need not represent sounds. We must remember that in his early manhood Mr. BLACKIE, as if he were to the manner born of a German student, undertook a long journey through Europe. In Italy his days were spent among artists, and from them so receptive an intellect was certain to receive impressions which were useful afterwards in many ways. He also practised drawing, which would help him in his efforts to acquire knowledge through what JOHN BUNYAN calls "eye-gate," and to test subjective subjects by endeavouring to impart a sort of objective form to them. Professor BLACKIE, in a characteristic way, began his treatment of art by an explanation of what the Platonic theory of beauty appeared to be to his mental vision. In the first place, he knocked down without mercy all the transcendental notions which have been supposed to be the only expressions of the quality. Like BURNS, he believed in a "sonsie" figure as the most perfect manifestation of beauty, for he wrote, "A full and well-rounded fleshly presentation is the natural and

only effective exhibition of a full and exuberant vital force." He was not guilty of self-admiration when he was writing about the effects of exuberant force, for the Professor was one of the thinnest of men. It was natural, however, that as he was endowed with enough vitality for half a dozen people, he should give the primary consideration to the motive power rather than to its effects. Mere statuesque beauty was of little account to Professor BLACKIE, unless he could trace in it the relation between cause and effect. He said, "It belongs to the order of nature, and to that finely-balanced system of significance between the inward forces and the outward shows of all existence, by means of which an expressive and cognisable world is made possible; and we have no more right to imagine this order of things reversed than to suppose that the planets might leap by lawless whim from their calculated courses, or the seed of an oak, when planted, grow into a gooseberry bush."

With a belief of that kind he could not believe in any one ideal of beauty or the repetition of particular types by an artist. According to the Professor, "The imitator of nature must know how to represent not merely her general types, but the endless variety of special modifications of those types so far as they by malformation or misfortune may not have sunk down into the domain of the ugly." The theory lends itself to what is now called realism in art, and it is remarkable that northern logic could find Platonic authority for such a result. Figures like those Professor BLACKIE admired would be interesting to all who were competent to trace in them the effects of certain hidden causes. In other words they would be symbolic, inasmuch as they would to the initiated stand for something else. The "full and rounded fleshly presentation" would recall a healthy atmosphere, nourishing food, adequate exercise, a contented mind and so on, all of which kept the subject from presenting an appearance of a different class. This recalling is, however, nothing more than an exercise of the association of ideas. Yet if there was one principle or notion among all those forming the stock-in-trade of philosophers which Professor BLACKIE abominated, it was that same association. ALISON and JEFFREY, who built a theory of beauty on it, would, we fear, obtain rhadamanthine justice if the Professor could have the settlement of their destiny. In all this Professor BLACKIE was only demonstrating his human nature by its contradictoriness. He hated association, and there is hardly a problem he advanced concerning art which does not depend upon it. The principle of association can be abused like all else that is good, and it has been made a sort of general utility actor whenever there is a difficulty in accounting for any of the scenes in the drama of life, but within its own sphere it is effective.

Professor BLACKIE's way of looking at buildings exemplified the power of association over him. With his affection for vitality it was only natural that his thoughts should run to the old builders at the sight of their work. An ordinary writer would trace the progress of architecture by saying first came the lintel, next the semicircular arch, and then the pointed arch, as if lifeless forms possessed a power of evolution. Professor BLACKIE in the following passage gives the prominence to the builders:—

The Egyptians and the Greeks—not from any historical connection that is either probable or provable, but following a natural instinct and a plain law of early construction—adopted the horizontal as the dominant line of their architecture, of which, combined as it was with substantial masonry, stability, solidity and permanence were at once the expression and the effect, and this feature the Egyptians wedded to the sublime and the Greeks to the beautiful, in a fashion and to a degree that no other nation has been able to surpass. After this the Roman builders—unless, indeed, they were content to remain servile copyists—had two courses open, either to strike out a new line altogether by means of their great instrument the arch, or to give the Greek parallelogram an altogether new character, by taking the triangular line of the pediment as their type, turning the obtuse angle of the apex into an acute, and repeating this feature on two or three platforms, so as to make a certain aerial lightness and elevation, not weight, mass and stability, the dominant expression of the whole. In the former case the Byzantine temple (of which St. Sophia at Constantinople and St. Mark's at Venice are the most familiar examples) was the result; the other style culminated by various gradations into the Gothic.

When he saw one of the great Egyptian temples his wonder was not restricted to the quantity of stone before his eyes. He thought of the men who displayed such appreciation of the principle of magnitude, and who contrived to be graceful when employing masonry on the

largest scale. And then, as he dwelt on the power of the Egyptians who could plan and execute colossal works, the Professor was able to realise that they were not such miserable idolaters as they are described to be whenever it is considered necessary to improve the occasion of a visit to Egypt under clerical auspices. To his mind great activity in any of the arts asserted a remedial influence over men, and from what he knew about the Egyptians he was able to imagine that their decoration was as inspiring as the "Iliad" to the Greeks.

What these titanic structures speak to us, addressing as they do only our æsthetic sensibilities, falls infinitely short of what their significance must have been to the loyal and religious spirit of the ancient Egyptian. Here on these walls, which to us are only scrawled with strange human figures, monstrous gods and alphabetic symbols, to all but a few of the curiously learned as mute as the stones on which they are chiselled, the citizens of the great city of Ammon read with reverent awe and patriotic admiration the offices of their most revered deities and the virtues of their most famous monarchs. These walls, in fact, stood before them constantly in bright public display, as at once the Bible of their faith and the "Iliad" of their history. Nor was their faith, as painted or symbolised on those long lines of significant wall, anything of which, as compared with other polytheistic peoples, they had any cause to be ashamed. Gods with the heads of cows, dogs, cats, crocodiles and hawks of course appear strange and belike ridiculous to us; but this is only because we ignore their symbolism, and are un instructed in their significance. Let any man only consider what a part animals have played in the symbolism of human thought, from the fables of Pilpay in the East to Esop in the West, and he will understand that the cats and the crocodiles, the hawks and the bulls and the dogs of old Egyptian religion did not receive the pious homage of their worshippers without a cause. The error consisted—and it is an error which makes their sublime shake hands only too familiarly with the ridiculous—in confounding the symbol with the thing signified, and in making an incarnation of what was originally only a typified function.

He was less satisfied with the representations of the Etruscan painters because there was no guide, no Rosetta stone to suggest the meaning of the artists. But what he saw of ancient art in Egypt, Greece and Italy, made him grieve when he contrasted it with what he saw in his native country. Professor BLACKIE was one of the severest censors of those Scottish clergymen who used to regard the arts as demoniac agencies. If there is a difference in the character of the churches, and the architect's work is considered to be as orthodox as the village mason's, the change is in some measure to be attributed to the Professor's influence. Nor was he less opposed to laymen's buildings when they were set up without any thought of the debasement of the landscape. There was no man who was better acquainted with Scotland, for he was a confirmed pedestrian, and when a hotel or hydropathic establishment, having as much architectural form as a packing-case, was erected in one of the picturesque spots, it caused him pain which he could not endure in silence. Many a bitter letter was penned by him on the subject.

Professor BLACKIE might refer to himself as an example of his theories of knowledge. If he devoted his long life to the niceties of scholarship he would have come nearer to the ideal of a professor as it appears to the majority. He believed, however, that scholarship is barren unless it leads to action, and accordingly his exertions for various purposes were untiring, and generally they were profitable to his countrymen.

THE LATE HYDE CLARKE ON COLOUR.

THE late Hyde Clarke, who died a few days ago in London was known of late years as a financier. He was also an erudite student of the science of language. Between fifty and sixty years ago he had gained a reputation of another sort. At that time he was a prominent writer on engineering and architectural subjects. He was, too, one of the pioneers of technical education, and we believe he took charge of a class for colour decoration. One of his papers on colour may be considered to have some interest, especially as in it Mr. Clarke broached the supposition of a relation between colour and electricity.

At the present period, when so much interest is excited as to the decoration of our public buildings, and when a better epoch for this department of art seems opening, the subject of the laws which regulate it can scarcely fail to be attractive to the profession. I should first wish to call attention to M. Chevreul's theory of contrast, with some few remarks I have to make upon it. M. Chevreul says that where the eye sees at the same time two contiguous colours it sees them as dissimilarly as possible, both as to their optical composition and

as to the depth of their tone, so that there may be at the same time simultaneous contrast properly so-called and contrast of tone. Thus if two colours *a* and *b* are in juxtaposition they will differ as much as possible from each other when the complement of *a* is added to *b* or the complement of *b* added to *a*. If we choose for our experiment orange and green, and if we place orange by the side of green, blue, the complement of the orange, is added to the green, which thus becomes more blue and less yellow, and so similarly the red, the complement of green, is rendered more vivid in the orange, which also becomes less yellow. M. Chevreul has not suggested the cause of this remarkable phenomenon, but I am myself inclined to attribute it to a tendency which the colours have to balance each other in a manner like to that in which heat diffuses itself from a heated body to one of a lower temperature and similar to the law of electrical distribution. If this should be the case it would also be confirmatory of a homogeneity of colour, which many other circumstances would lead us to believe, so that light, instead of being considered to be composed of three simple coloured rays, would, according to that view only, owe the phenomena of colour to the different arrangement of its particles, as ponderable substances, according to the arrangement of their molecules, vary their forms. Colour, perhaps, after all is only dependent on electrical action, and could we establish this our way would be clear to the production of coloured representations by electricity, instead of the present daguerreotypes and to many of the operations of dyeing.

Pursuing his remarks, M. Chevreul says that it is evident that the phenomena of simultaneous contrast would increase the brightness both of *a* and *b*, and make them appear more brilliant than they would when looked at isolatedly. If the colours brought together belong to the same group of rays, and only differ in intensity, the clearest in tint will appear still clearer at the point of contact, while that deepest in shade will appear deeper, the tints will be regularly affected from the point of junction, the one set lighter and the other deeper. Coloured and white bodies, when put in juxtaposition, become, the former more brilliant and deeper, and the latter of the complementary colour of the others. Thus green and white: red, the complement of the green, is added to the white, and the green appears deeper and more brilliant. In the juxtaposition of coloured and black bodies the effect of the contrast of intensity is to deepen the black and lower the tint of the juxtaposed colour; but a very remarkable fact is the weakening of the black itself, when the juxtaposed colour is deep, and of such a kind as to give such a bright complementary colour as orange, yellowish orange, greenish yellow, &c.; for instance, with blue and black, orange, the complement of the blue, is added to black, the black becomes lighter, and the blue is clearer, perhaps greenish. All grey bodies contiguous to coloured bodies may present the phenomena of contrast in a manner more sensible than white and dark bodies do. Thus yellow and grey: the grey takes more of a violet cast by receiving the influence of the complement of the yellow, and the yellow appears more brilliant and yet less greenish.

Besides this simultaneous contrast of colours, M. Chevreul distinguishes a successive contrast of colours, by which he means all those phenomena which are observed when the eye, having for some time looked on one or more coloured objects, perceives after having ceased to look at them images of these objects presenting the complementary colour which belongs to each. He also defines a mixed contrast, which is the result of the two others; it takes place when, having looked at a red paper, for instance, and we turn towards a blue, it will appear greenish; if, on the other hand, we look first at the blue and then at the red, the red will appear orange. These are all well known phenomena, but M. Chevreul makes a practical application of them; he recommends the painter not to keep his eye too long fixed on his model, and the purchaser of coloured goods to be similarly careful if he wishes to keep his eyes in a normal state to look at the last pattern, otherwise the several patterns will, after the first, appear faded and less fresh in colour, although they may all be of the same quality. A shopkeeper who shows several silks, say red, should show others of a complementary colour, green in this case, in order to restore the eye to its normal state, and better to prepare it for the red, by making the red look more brilliant than it really is.

I shall now make another halt to give a hint to those of my readers who consult French works as to the use of several words used by the authors; thus, *ton* we call intensity, tint and shade, *gammes*, the key colour or tone, and *nuances*, hues. Two or three useful rules I shall also advert to here. The best contrast, it must be remembered, is produced by the complementary colour, and all colours must be of the same intensity.

When two colours do not agree it is best to separate them by white. Black is also useful for this purpose when applied with bright colours, and, in some cases, preferable to white.

Black may be advantageously applied with sombre colours and with some of the dark tertiaries.

It will now be necessary to consider the several colours separately, in doing which I shall principally avail myself of Mr. Hay's work on colour, the best and cheapest practical work on the subject, and one which to the professional man and to the student is indispensable.

Like Mr. Hay I shall begin with white, the representative of light, which is regarded as produced by the reflection of the three primary colours simultaneously in their relative neutralising proportions. Although there are eight kinds of whites, there is only one which is understood as a pure white. Its contrasting colour is black, being opposite to it in the scale, but the arrangement in which its effect is the most happy is with blue and orange. In the series it lies nearest to yellow, which may be adopted as its melodising colour. With nearly all colours, however, it harmonises in conjunction and opposition, and to its properties in separating two discordant colours I have already referred. It does not agree so well as grey with red and orange, and with blue, violet, &c., it is harsh. It is to be preferred to grey with yellow and blue, also with red and green, red and yellow, orange and yellow, orange and green, and yellow and green. With very light primrose, yellow forms an agreeable arrangement. All colours brought in contact with pure white must be light and cool, amongst which grey and green may be employed and intense or rich colouring must be avoided. A south light is the best for white, which, when it is the predominating colour for a room lighted from the north, should be made of a cream colour, so as to get rid of the cold reflection as far as possible.

French white is, properly speaking, the lightest shade of purple, and is seldom used in house painting, but Mr. Syme says that he has seen it made the prevailing colour of a drawing-room in a country residence with good effect. It can only be introduced when all the other colours are light and cool in tone, as any quantity of intense or rich colouring completely subdues it.

Black, the representative of darkness, is regarded as produced by the absorption of the three primary colours, simultaneously in their relative neutralising proportions. In the series it lies next to purple, which may be considered as its melodising colour. Its contrasting colour is white, we may also add yellow, but it is most happy in combination with red and green, red and yellow, orange and yellow, orange and green, and yellow and green. By being associated with sombre colours, such as blue and violet, and with the lower tints of the bright colours, it may be often made to produce a very good effect. It is always happy when used with two bright colours, as orange, yellow, red and bright green. As a separating colour it is often to be preferred to white. It is not so good as grey in combination with orange and violet, green and blue, and green and violet. It is only in arrangements of a cool and sombre character that it can be used in large quantities, and it is recommended to be used always pure and transparent. The ancients used it happily and in great profusion, and in the monuments of the Egyptians, the vases of Greece and Italy, and the decorations of Pompeii and Herculaneum. We find it in combination with the brightest colours, often used as a separating colour or as a contrast, and always with effect. Mr. Hay recommends great caution in the use of both white and black, for being at the top and bottom of the scale they are very dangerous colours to manage. Where gorgeousness is the object, they must not be brought in.

Pure yellow, of the power of 3, which Mr. Hay calls yellow jasmine or a deep lemon hue, is the lightest of the three primary colours and the nearest to white. Its contrasting colour is purple and it forms a strong contrast to black. Its melodising colours are orange and green, which are the secondaries it forms with red and blue. Its ternary is citron, and its quaternary is brown and marrone. Being the most powerful of the primary colours, it is most offensive to the eye when used extensively in a pure state. With red, orange or green, it does very well in combination with black and even with grey. In artificial light yellow, it is well known, appears to be of less intensity, as is the case with all colours into the composition of which it enters.

Primrose, which is a very light yellow, forms a pleasing arrangement with pure white, being a light and cool colour.

Red, of the power of 5, is, by Mr. Hay, represented to be of the most intense geranium colour, and as difficult to be defined. It is the second of the primaries, a very warm colour, and the most positive of all colours, pre-eminent among them. Its contrasting colour is green. The secondaries with which it melodises are its combinations with yellow, forming orange, and with blue, forming purple. Its tertiary is russet and its quaternary is marrone and slate. With another bright colour it forms a good arrangement with black, as it does also when combined with yellow. Being a warm colour, it acts upon all colours brought in contact with it or into which it enters, and must not be used on a large scale uncombined, requiring great skill in its use. It is heightened by artificial light. It is considered to be an excellent key colour, and, when so used, it is recommended that its contrasting colour,

green, should be neutralised by being brought down in tone towards olive.

The nearest hue of red towards yellow is scarlet, which is very brilliant, and requires much the same management as orange. It must never be used in large masses, except under very peculiar circumstances. Its contrasting colour is a bluish green. The ancients used black with scarlet.

The nearest hue of red towards blue is crimson, one of the most gorgeous, at the same time most cool and mellow, and very useful as a key colour. Its contrasting colour is a citron green, and its melodising colours a bluish green and reddish purple.

Pink is the next hue after crimson, and is very useful for heightening reds in cool-toned arrangements.

Blue, of the power of 8, is the deepest of the primary colours, and the nearest in relation to shade. It is a cool colour, acting upon colours used with it, and may be employed in masses with much less glare than either of the other primaries. Its contrasting colour is orange. The secondaries with which it melodises are its combinations with yellow, forming green, and with red, forming purple. With green, however, blue is very discordant, more so than any primary with its secondary. Its tertiary is olive, and its quaternaries slate and marrone. With orange it makes a good arrangement with white, and with green agrees with grey, and with violet it enters into composition with black. Black may be very advantageously used with it under many circumstances. White and blue are apt to appear raw in contrast. When used with green and olive, on account of the discord blue requires the interposition of grey or of some other neutral colour; with olive a purple grey may be used. Blue is reckoned a good key colour where a refreshing appearance is desired; with artificial light, however, it is chilled. We now come to the secondaries.

Orange is a compound of yellow 3 and red 5, being of the power of 8. It is one of the most brilliant colours there is, and the contrast to blue; it requires therefore to be used with a sparing hand, although it is reckoned a good key colour. Olive also forms a contrast with it. It is the melodising colour to yellow and red, and is itself melodised by its tertiaries, citron, formed with green, and russet with purple. It is acted upon by artificial light much in the same way as yellow is. With blue it may be combined with white, and with red, yellow or green may be used with white or black. With more yellow the hues orange forms are gold, giraffe, &c., and it then requires for its contrast purplish blue.

Green is the coolest of the medium of the secondaries, and is composed of yellow 3 and blue 8, being of the power of 11. Its contrasting colour is red, and also russet. Green melodises with yellow and blue, and is itself melodised by the tertiaries citron, formed with orange, and olive with purple. It is one of the worst colours under artificial light. With red, orange or yellow it may be used in composition with black or white, but with blue or violet grey is to be used. Being such a soft colour, green may be used in quantity without fear. It requires great care when used with blue, and should be separated by a neutral tint.

Purple is one of the darkest colours most nearly allied to black; it is of the power of 11, and is composed of yellow 3 and blue 8. Its contrasting colour is yellow, and the tertiary citron, which is much used with it. Purple melodises red and blue, and is melodised by its tertiaries russet formed with orange, and olive with green. It is a cool colour, and it suffers much under artificial light, but next to green it may be used with the most freedom. With green or orange it may be used, with grey and with blue black is to be used. With white its combinations are very raw.

Indigo is the first hue, formed by blue on its union with red, and is a heavy colour little used, except in wove fabrics.

Purple forms various hues as lilac, &c., with which citron may be advantageously used.

Grey is a neutral colour, and enters with effect into many combinations, being the medium between light and shade. It is very useful in separating blue from green or olive. Its most happy combination is with red and orange, and with orange and violet, green and blue and green and violet.

To proceed to the tertiary colours.

Citron is a tertiary colour, in which yellow predominates; it is composed of orange 8 and green 11, being of the power of 19, or yellow 6, red 5, blue 8, its contrasting colour is purple and also slate; it melodises with orange and green, and is melodised by the next series, brown formed with russet and marrone with olive. Citron is greatly relieved and harmonised by olive. It is soft and pleasing to the eye and is the lightest of the tertiaries, much used as a contrast amongst low hues of crimson and purple.

In russet red predominates, being composed of orange 8 and purple 13, of the power of 21, or yellow 3, red 10, blue 8. Its contrasting colour is green and also marrone. It melodises with orange and purple and is melodised by the next series, brown formed with russet and slate with olive. This tertiary is of great use and particularly with green.

Olive has blue for its predominant constituent and is composed of green 11 and purple 13, being of the power of 24, or yellow 3, red 5, blue 16. Its contrasting colour is orange and also brown. It melodises with green and purple and is melodised by marrone formed with citron and slate formed with russet. Olive has a great relation to shade, and is characterised by Hay as soft and unassuming, being of great use in all arrangements, whether cool or warm, being employed with the lower hues of warm toned or brilliant composition. It must not be brought in contact with blue but separated by grey.

The next rank is held by the quaternaries or semineutral hues. These are:—

Brown composed of citron and russet, of the power of 40, consisting of yellow 9, red 15, blue 16. Its contrasting colour is olive. It is a most useful colour in the low parts of warm-toned arrangements.

Marrone is composed of citron and olive, being of the power of 43, or yellow 9, red 10, blue 24. Its contrasting colour is russet. This semineutral is most useful in wove fabrics. It is considered to be deep and clear, and although allied to red, may be used where there is a preponderance of cool-toned colours.

Slate is the deepest of the semineutrals, and is composed of russet and olive, being of the power of 45, or yellow 6, red 15, blue 24. Its contrasting colour is citron, and it can only be used in cool-toned arrangements.

THE NEW ROYAL OBSERVATORY, EDINBURGH.

ON Saturday afternoon the members of the Edinburgh Architectural Association paid a visit to the new Royal Observatory, which is nearing completion on Blackford Hill. The company met at the observatory at three o'clock, and there they were joined by Mr. W. W. Robertson, H.M. Board of Works, president of the Association and architect of the building, and Professor Ralph Copeland, the Astronomer Royal for Scotland.

The Astronomer Royal, in welcoming the members of the Association to Blackford Hill, said that although none of the larger instruments were yet in position they would at least see the arrangements that had been made for their reception, and for the pursuit of astronomical research. He trusted that the study of astronomy in these fine new buildings would flourish, and that the excellent work which was carried on by Professors Henderson and Smythe would continue.

Mr. Robertson then gave a short description of the main portions of the building. He said that in 1888 Lord Crawford of Balcarres offered to give his whole astronomical equipment at Dunecht, including the library, which contained over 15,000 volumes—the finest in Europe except, he believed, one in Russia—as a gift to the nation. This gift necessitated the erection of a new Observatory. The Government appointed a committee of experts to advise on the selection of a site and the arrangement of the buildings. After considerable deliberation the present site was selected and the Town Council granted them four acres of ground at a nominal price. The site chosen had the advantage of being free from the smoke and haze of the city, it had a perfectly free view of the horizon all round, with the exception of a small portion which lies towards the south obscured by the ridges of the Braids and Pentland Hills; and the horizon in the meridian was perfectly free. Professor Copeland had by means of minute experiments proved that the Observatory would be perfectly free from vibration.

The buildings included the Observatory proper, the Astronomer Royal's house, houses for the assistants, and a gate-lodge for the mechanic, as well as stabling accommodation. The T-shape of the buildings had been chosen in order to give the Observatory a clear outlook, so that the instruments could be placed in such a position as to sweep the whole horizon round. Then the transit house, which was one of the most important portions of the Observatory, was placed about 80 feet from the main building. The first reason for that was in order that they would keep the meridian line clear from the other buildings. A covered way connected it with the main building, because it was absolutely necessary to good observing that the observer should reach his work dry-shod. The walls of the transit house consisted of two thicknesses of metal with an inner and an outer covering of corrugated iron. The most complete arrangements were made to maintain an equal temperature, which was a very important consideration in such a place. Turning to the main building, Mr. Robertson said the largest of the two domes was intended for the large equatorial telescope from Dunecht, and the smaller dome would contain the smaller equatorial from Calton Hill. He pointed out that the disposition and character of the building was entirely governed by scientific and not architectural considerations. The main workrooms of the Observatory were in the principal front facing the north. After walking round the

building the company entered the transit house, where Professor Copeland said that the purpose of the department was simply for observing the time of day from the sun or from the heavenly bodies. The piers for the large instrument to be used in the room are of Dunecht granite, and weighed about 15 tons. The greatest care was taken to adjust the piers for the telescopes, and that was done by means of another instrument. The work of making the piers perfectly equal was performed with such exactitude that there was not a difference between them of a fraction of the thickness of a piece of tissue paper.

Passing along the covered way to the main building, the company visited in turn the photographic-room, in which there were three heavy piers to mount the instruments. Here also are the piers on which will stand the instruments and mean time clocks which will henceforth provide Edinburgh and Dundee with the time of day. The library, designed to contain 20,000 volumes, was inspected, and thereafter the party visited the optical-room, which can be rendered perfectly dark at a moment's notice. Here Professor Copeland said the room ran exactly north and south, and adjoining it to the north was a broad terrace right over the library, from which an observer can view the whole vault of the sky. In the northern end of the room he said there was a small window fitted to receive lenses of any size, and by means of these lenses and a powerful silverised mirror driven by clockwork outside on the terrace sunlight can be thrown into the dark room. Then in this room they could analyse the sunlight and photograph it, and they could also analyse the light of the moon or of the stars or the planets. The instruments would be mounted on carriages running on rails, which had an entirely separate existence from the floor to prevent false movements. On some of these carriages they could mount instruments of more than a ton in weight, and they could adjust these instruments to a very hairbreadth.

Arriving out on the terrace the party first visited the small or western dome, which, like its larger neighbour facing it in the east, is covered by an outer thickness of copper. The interior of the tower was reached by means of a narrow spiral stair. The equatorial telescope from the Calton Hill will be placed in the western dome, which revolves by means of ingenious mechanism, enabling the observers to sweep the whole range of the heavens through the opening provided in the side of the dome. The weight of a small iron brick is all that is necessary to start the revolving drum, which weighs nine tons, so exact is the mechanism. The other dome, which is of very much larger dimensions, revolves on the same principle. It will contain the large equatorial telescope, from the observations with which Professor Copeland anticipates many beneficial results. The drum of the large dome weighs 17 tons. Under it are stored 3,500 gallons of water for the use of the small colony of observers. Professor Copeland pointed out that the dome of 17 tons weight was easily and noiselessly made to revolve by means of a brick weighing 30 lbs.

In the large dome refreshments were provided, and thereafter Mr. Robertson proposed a vote of thanks to Professor Copeland. Mr. Ross seconded. Mr. Balfour Paul proposed a similar compliment to Mr. Robertson, and both were heartily awarded.

Professor Copeland afterwards took a number of gentlemen who, for the occasion, were unprovided with watches, to see his wonderful electro-magnet, which is fitted in a room in the basement. The magnet is the largest in the world, and Professor Copeland said that it exhibited not only the usual attraction on iron in its various forms, but also showed remarkable effects on copper and other metals usually classed as non-magnetic. Any person entering the magnet-room with a watch would regret it, as the magnet assuredly would effectively destroy it. There was no great danger in working the magnet at the start, but when once set agoing it could only be stopped with difficulty, culminating in a great flash, which did the damage. With this last sight of the wonders of the Observatory the visit ended, and the party returned to the city.

THE TEMPLE OF PHILÆ.

AT the last meeting of the Newcastle Society of Antiquaries Mr. R. C. Clephan read a paper on "The Temple of Philæ, and the danger of Submersion by a projected Dam, with Introductory Notes and History of the Temple, and Religious and Social Life of the Ancient Egyptians." The temple, he mentioned, was on a granite rock 1,000 yards in circumference, and situated a little above the first cataract of the Nile.

Mr. Holmes said this question of the Philæ temple was important at present. The engineers asserted that it was necessary, for the good of Egypt, to destroy the temple. The archaeologists said it must not be destroyed. As a compromise, it was proposed to inundate it. He supposed the temple would be left above high-water mark. It would therefore, at anything but high-water mark, be surrounded by a bank of slime, which would thicken until it became a sea of mud. The

value of swamping the temple was, however, in his opinion, more than the value of retaining it.

Mr. Clephan said he was very much afraid that the levels were not correct, and would carry the water up into the main temple. Lord Cromer had stated that the work was beginning now, and would be pushed forward over a good many years. He (Mr. Clephan) was quite sure that the expense would be so enormous that the advantage would be problematical.

Mr. Holmes remarked that there was this difficulty, that the site which would destroy the temple was about the only site affording an absolutely secure base for an embankment or dam. The French put up an erection which the English had to correct and make useful; but notwithstanding all their care the foundations were faulty. Anything founded in the Nile mud was almost sure to be undermined. The effect of this at that part of Upper Egypt would be to swamp the whole country, with the enormous accumulation of water they had there. Therefore it was absolutely necessary to have the dam on the rock site at the Temple of Philæ.

Mr. Clephan admitted that there was great weight in what Mr. Holmes had said, but the question was a very large one, and should not be hastily decided on.

LAKE DWELLINGS.

AT the last meeting of the Edinburgh Royal Society, Dr. Munro gave a sketch of "Lake Dwelling Research." He said that whatever may have been the primary object of lake dwellings, or the circumstances which led to their development, one thing was certain, that they had for many centuries been characteristic abodes of early inhabitants of Central Europe. He went on to describe the circumstances which led to the discovery of the sites of so many of those ancient dwellings, and to convey a general idea of the extreme wealth of archaeological material brought to light by subsequent investigation. The actual starting-point of research might be dated, he said, to the discovery of certain remains in a bog in Ireland upwards of half a century ago. Having explained the nature of the relics, he stated that an independent discovery was afterwards announced in Switzerland, which not only gave new significance to the Irish discovery, but opened up one of the most prolific fields of historic research that had ever come under the cognisance of archaeologists. He rapidly sketched the results of investigation made on the sites of the Swiss lake dwellings during the past thirty or forty years, afterwards treating of the concurrent researches instituted in other parts of Europe, special attention being directed to Italy. He stated that perhaps no locality in Europe contained a greater variety of the vestiges of past humanity than the valley of the Po. Having given interesting details of continental investigation, he said that the spirit of research stimulated archaeologists everywhere. Passing on to deal with such investigation in Scotland, he explained that the first great discovery was made in a loch in Wigtonshire. The loch was drained, and several artificial islands emerged, the antiquarian remains collected disclosing a picture of Scottish civilisation previously unknown to historians or archaeologists. Among the remains were canoes, bronze dishes of Roman origin, bracelets and other ornaments. After referring to subsequent finds in Scotland, he spoke of the recent discoveries of lake dwellings in Bosnia. In concluding, he said that the coincidence in the style of art in the ornaments recently found at Glastonbury with those obtained in Northern Germany was of peculiar significance to ethnologists and archaeologists.

FLORENTINE ART.

A LECTURE on "The Romance of Florentine Art" was delivered lately by Mr. Arthur Lee in the Bristol Museum. He said that in the Florence of Dante, Petrarch and Boccaccio they felt almost at home. With the men and women of that time they could feel much in common, as their manner of life and their ways of thinking were not so widely different from our own. After describing the beauty of the city and the building of the earlier bridges which span the Arno, the speaker proceeded to give a description of the great cathedral and its builders. The history of the building was traced, including the International Conference of Architects which took place when the plan of the dome was debated. After a short historical account of the baptistery of St. John, with a description of the great bronze gates and the "Jericho" panel, Mr. Lee stated that the Palazzo Vecchio was built by the Florentines for the Priors to live therein during their term of office. This was when the Florentines were making a most important political experiment. A little more than 600 years ago they resolved to do away for ever with the power of their nobles. They abolished their "House of Lords" root and branch. Twelve citizens called Priors were elected by popular vote. To them was entrusted the whole conduct of affairs. Never again,

resolved the Florentines, under any circumstances would they allow a ruling class to be evolved, so it was seriously resolved that a general election should take place once in two months. The Priors retiring from office could not be re-elected. The hereditary principle was recognised, but only in the way of creating disabilities. A son could not be elected under two years after his father had served. It was enacted that every man must be a tradesman, or at least a member of some trade guild, otherwise he must submit to be called a Scioperato or "Do Nothing," and as such he was excluded from all participation in the government. Florentines did not quite rise to the payment of members—he meant "Priors"—but they lodged them and fed them at the public cost, which was perhaps next door to the modern proposition. The power of the Priors was limited. They could administer but could not legislate. In grave matters it was their duty to call all the people into council. But all this jealous care was of no avail, and the most democratic Government which the world has ever seen fell by its own defects. There were violent and sudden changes of public opinion, and the career of the Medici family was one of the most remarkable instances where the popular voice alternately raised them to the highest power and then made them outcasts. Cosmo de Medici filled in turn every important office in the gift of the people, but in 1433 his enemies secured the popular support and drove him from the city. Within a year of his banishment he was called back again by another popular vote to put an end to this experiment, amid popular acclamation, and he governed the city until the time of his death as an absolute ruler. After describing the casting of the *Perseus* by Benvenuto Cellini, the Florentine Public Library, the University and the habits of the students, Mr. Lee touched on the building of the Pitti Palace and the fall of Luca Pitti, who swiftly fell from popular favour into dire disgrace. The failings of the Florentines were forgotten, as they honoured the evidence of their genius, and the Florence of the Middle Ages was borne in men's minds to-day not so much by reason of the work of her warriors and statesmen as by that art which was the deathless creation of her painters, her sculptors and her poets. The lecture was illustrated with a number of dissolving views.

THE LATE SIR H. RAWLINSON.

ON Tuesday Sir Henry Rawlinson, who had so often escaped imminent death in the East, succumbed to one of those chills to which warriors and statesmen are as liable as ordinary men. To speak of Sir Henry Rawlinson as a man of science in any adequate fashion, says the *Times*, would fill a volume. As is well known, Sir Henry, when he first went to Persia in 1833, spent much of his time in tours through some of the remoter districts of the country. In 1837 he wrote an account of a tour through Susiana and Elimalis. This he supplemented with a description of Ecbatana, which gained for him the gold medal of the Royal Geographical Society. He began as far back as 1835 to copy down the cuneiform inscriptions on the rock tablets at Behistun. He had achieved no inconsiderable results, and was on the threshold of complete success when the Afghan war summoned him elsewhere. On his appointment to Bagdad he renewed his connection with Mesopotamia, and found that the excavations at Khorsabad, conducted by M. Botta, the French Consul at Mosul, had facilitated his task. The archaeological remains found there in abundance showed that all the Assyrian legends were described in ancient Persian translations. By mastering the old Persian character on the tablets at Behistun he found the key which eventually deciphered all the memorials of Assyrian history. The years 1844 and 1845 were specially devoted to this task, and in 1846 he published his first work on the cuneiform inscriptions. In 1847 he obtained by incredible personal exertion and not without risk, as the most important inscriptions were on a precipitous rock 300 feet above the plain, complete copies of all the inscriptions. In 1849 he paid a visit to England after an absence of twenty-two years, bringing with him the copies mentioned. A very short time after his return to England he read the celebrated paper on the cuneiform inscriptions of Assyria and Babylonia, in which he gave the first translation of the "Black Obelisk Inscription." This paper was followed up by his discovery among the inscriptions just brought home by Mr. Layard of a mention of the war between Hezekiah and Sennacherib. In 1851 Sir Henry Rawlinson was granted the sum of 3,000*l.* by the British Museum for the purpose of systematic excavations, in which he employed Mr. Hormuzd Rassam and several others. These excavations were carried on with equal ability and caution. Many of the sculptures are to be found in the British Museum, and, although no regular history exists of these efforts and their results, there is much to be learnt on the subject from contributions by Sir Henry Rawlinson and others to the Asiatic Society's journal between the years 1852 and 1856. In

Germany Sir Henry Rawlinson's claims to be regarded as the first decipherer of the cuneiform have always been allowed without hesitation, notwithstanding the labours of Lassen and others in the same field, and among the earliest and most cherished of Sir Henry Rawlinson's foreign orders was the Prussian Order of Merit.

TESSERÆ.

Pneumatics and Foundations.

IT is said that Papin, the eminent physicist, born at Blois in 1647, conceived the idea of employing a continued supply of compressed air to enable workmen to build under a large diving-bell. In 1779 Coulomb presented to the Paris Academy of Science a paper detailing a plan for executing all sorts of operations under water by the use of compressed air. His proposed apparatus was somewhat like that now in general use. In 1831 Earl Dundonald, then Lord Cochrane, took out a patent for a device for sinking tubular shafts through earth and water by means of compressed air. His air-lock was much like modern ones, and was to be placed at the top of the main shaft. His invention was made with a view to its use in tunnelling under the Thames and in similar enterprises. In 1841 Bush also took out an English patent for a plan of sinking foundations by the aid of compressed air. A German, by name G. Pfaun Muller, made a somewhat similar design for a bridge at Mayence in 1850; but as his plan was not executed, it was, like the patents of Cochrane and Bush, little known till legal controversies in regard to patent rights dragged them from obscurity. The first practical application of the plenum process was made in France in 1841 by M. Triger. In order to reach a vein of coal on a sandy island in the Loire, opposite to Chalons, he sunk an iron tube about 40 inches in diameter some 60 feet by the blows of heavy weights. The fine sand was removed from the interior by means of a scoop-bucket. On reaching a layer of coarse gravel, he could not force the tube through. He therefore capped his tube with an air-lock, and by compressed air forced out the water which had all the while filled the tube, and sent workmen to the bottom. The pressure he used was never greater than two atmospheres. The water was discharged through a small tube, into which, several feet from the bottom, a jet of air was allowed to enter, thus diminishing the specific gravity of the column till it was rapidly blown out. In 1845 Triger read a paper on the sinking of a tube about 6 feet in diameter to a depth of 82 feet by the same method, and suggested the use of it for the construction of deep foundations for bridges. Dr. Potts generally has the credit of inventing the vacuum process, for which he took out a patent in 1848. Many times in sinking foundations by this method the compressed air process was resorted to so that men could enter the pile to remove obstructions, and finally its many advantages caused it to entirely supersede the vacuum process. At present the term "pneumatic process" is practically synonymous with compressed air process. The first foundations sunk entirely by the latter were the pneumatic piles for the bridge over the Medway at Rochester, put down in 1851. The depth reached was 61 feet. The first pneumatic caisson was employed at Kehl, near the eastern border of France, for the foundation of a railway bridge across the Rhine.

Floor Coverings.

In English houses in Elizabeth's days even the floors of banqueting halls and ball-rooms were covered with rushes, for Shakespeare says, that "Wantons light of heart tickle the senseless rushes with their heels." If the owner could boast of a carpet, it was reserved for the chamber or the parlour. Rushes not only allayed the dust, but served as a token of respect. "Are the rushes strewed?" asks Grumio, when expecting the arrival of Petruchio and his bride. On the floor were spread new rushes when guests were invited. It was an old joke among the wits of the Elizabethan age that many strewed green rushes for strangers who would not give a straw for a friend. To cover the floor, indeed, was deemed so necessary a point of courtesy that when not performed it was said that the host did not care a rush or a straw for his guest, hence the origin of an expression common now. The use of these homely materials pervaded all classes; even the hall of the virgin queen, according to Hentzner, was strewed with straw. Among the middle class this custom prevailed at a much later period, and the welcome associated by time-honoured usage with the strewing of rushes retarded the general introduction of carpets. Many retained the use of the homely herbage, whose wealth placed the looms of Italy at their disposal. Carpets, however, which during the Middle Ages were rarely found except in the homes of royalty, were gradually becoming less expensive. Beaumont and Fletcher's coxcomb does not forget among the luxuries with which he would have his house arranged, to specify the "Turkey carpets," the use of which was so opposed to the habits of the people that they were as

yet regarded as luxurious and foppish. Carpets of "Torquey makyng" and carpets of silk, covered, many of them, with beads and gems, were among the household treasures of Henry VIII. His Highness, just before his death, purchased of Lawrence Warren, merchant, "a very faire carpet." It was the most sumptuous "tapet" in the Royal household, being embroidered with venie gold and trails of pearls on a ground-work of crimson satin; it was edged with a deep border of gold and rows of pearls, and lined with green silk. Many of these beautiful carpets were the productions of English embroiderers.

Spanish Architecture in the Thirteenth Century.

As soon as the thirteenth century is reached we find a new native Arab style in the Peninsula, Moslem, no doubt, and entirely unlike the contemporary Christian architecture of Spain, yet distinctly and distinctively Spanish. And it is this style which in the hands of the descendants of those Syrian conquerors who founded a second Damascus at Granada reached its highest perfection on the ever-celebrated banks of the Darro. It was not until the Moslem art had well nigh forgotten the traditions of Byzantium and revelled in its own originality that it reached the highest pitch of perfection in the Peninsula. And if Granada did not enjoy the artistic supremacy in contemporary Europe that was universally allowed to Cordova, it was not so much that the Spanish Moslem was less powerful and his culture less directly influential, as that Europe had in two centuries become at once relatively and absolutely more civilised than before. The Christian Renaissance was at hand. Yet Granada was a centre of artistic culture, less magnificent and less powerful but no less truly artistic, and actually distinguished by a more characteristic originality and spontaneity of development than the Cordova of the greater Caliphs. Among all the buildings, not only of Spain but of Europe, the Alhambra at Granada has long been accounted one of the greatest marvels and exemplars of superlatively graceful construction that still lives to disarm the critic and to delight the lover of the beautiful.

The Exhibition of 1760.

The year 1760 was rendered memorable in the annals of British art by the opening of the first public exhibition of the works of modern painters, sculptors and architects. The result of this scheme exceeded the most sanguine expectations of the projectors. All ranks of people, says a contemporary writer, crowded to see the delightful novelty. It was the universal topic of conversation, and a passion for the fine arts was excited by this first manifestation of native talent, which has ever since been increasing in strength, and extending its effects throughout the length and breadth of the land. The history of English exhibitions affords of itself the strongest evidence of their effect upon the public taste. Although at their commencement some men of enlightened minds could distinguish and appreciate what was excellent, the admiration of the many was confined to the most puerile subjects and the meanest efforts of imitation. But these puerilities have long since ceased to produce astonishment and delight, even in the vulgar, and we see with surprise such trifling subjects as the following in the catalogues of the early exhibitions:—"A Corner Cupboard," "A Gazette in a Frame," "A Bunch of Flowers in Tent Stitch," "A Coach Panel," "A Cucumber," "A Lady in a Snuff-box." To this exhibition, which opened on May 21, in the great room of the Society for the Encouragement of Arts, Manufactures and Commerce, Reynolds sent four portraits of the Duchess of Hamilton, Lady Elizabeth Keppel, a Gentleman, and Lord Charles Vernon.

Decorated Belfry Openings.

The belfry windows and other windows in towers have usually a distinct character, and are frequently partially filled up with stonework, as at Aynho, Northamptonshire. Sometimes they may be called twin-windows, consisting of two single lights coupled together with a niche for an image between them, as at Irthlingborough and at Bloxham, Oxfordshire. The openings filled with tracery, but not glazed, which are found in some districts, especially in Norfolk (and there commonly called soundholes), sometimes occur in this style, as at Great Addington, though they are more common in Perpendicular work. The name of soundholes is not very applicable, as they are more strictly airholes; they are not used in the bell-chamber, but in the ringing-loft, to give air to the ringers. Those belonging to this style are generally smaller than in the next. They are sometimes diamond-shaped, but more frequently square. Triangular windows are likewise frequently used in the points of gables over large windows. Sometimes the common straight-sided triangle, more often the spherical triangle, as at Alderbury, Shropshire, and the Maison Dieu, at Dover. In the later examples these openings are filled with bar-tracery, the same as in the windows of other forms and sizes.

NOTES AND COMMENTS.

A CORRESPONDENT asks our opinion on the following point:—"I have just built a large hotel for a company, under ordinary contract stipulations, on a very exposed position. A storm of unprecedented violence struck the building (just before last Christmas) when I had the work nearly complete, doing great damage to the roof and window-glass. This storm completely unroofed other houses in the same town, and wrecked one new house completely. The architect attached no blame to me. The company had actually paid 80 per cent. of the money on account when this damage was done. The question now arises whether the company or I am to be liable for the cost of repairing the damage to slated roof and window-glass?" It is a principle of law that a contractor should carry out whatever he agreed to do, and as the hotel was, we suppose, to be delivered up in a complete condition as approved by the architect, our correspondent will, we are afraid, find it difficult to persuade the company to assume responsibility for the damage before they have possession. A hundred years ago a contractor who had undertaken to repair a bridge which during the operations was overthrown by an extraordinary flood, was compelled to rebuild the bridge. That precedent is still binding. The words of Mr. Justice (afterwards Lord) BLACKBURN are important:—"Where there is a positive contract to do a thing, not in itself unlawful, the contractor must perform it or pay damages for not doing it, although in consequence of unforeseen accidents the performance of his contract has become unexpectedly burdensome or even impossible." It might be pleaded that the maxim "*Actus Dei nemini facit injuriam*" applies to the case. That is interpreted by BROOM as meaning, "It would be unreasonable that those things which are inevitable by the act of God, which no industry can avoid, no policy prevent, should be construed to the prejudice of any person on whom there has been no laches." Storms as well as tempests and lightning come under that designation, which means, as Baron MARTIN said, "something overwhelming, and not merely an accidental circumstance." "Unprecedented violence" would not be readily admitted by any judge. Whether the storm which operated on the hotel would come under that term would depend on local evidence. In any case, it was one of those visitations which a man is bound to endure and cannot cast on other men. Meanwhile it will be well to remember that risks of damages for non-completion of the hotel are likely to be incurred while the subject is being debated.

For a long time the architects of the United States have been dissatisfied with the system adopted by the Government for designing and carrying out public buildings. In the department of architecture there are about one hundred employes. There is a legal division in which all business relating to sites, contract deeds, &c., is transacted. The technical division has to deal with designing, specifications, quantities and other calculations, and the superintendence of works. When it is remembered that the buildings are scattered throughout the United States, and range in value from 2,000 dols. to 4,000,000 dols., it is evident that to carry out the work efficiently is no easy task. The accountants' division has a corresponding responsibility. From time to time architects have assumed the office of supervising architect with a light heart, but only a short time is required for the strongest man who holds the office to be overwhelmed by his duties. If he is zealous, he gives dissatisfaction within as well as without his department, and he must not expect either loyalty or gratitude. Mr. CARLISLE, the Secretary of the Treasury, appears to be as eager about reforming the architectural department as a minister can be who must remember that if he meddles with abuses he turns voters against him. Accordingly he offered the post of supervising architect to Mr. CARRÈRE, who might be described as the representative of the architects in attacks on the department. Mr. CARRÈRE, however, considered the subject as became a loyal citizen, and endeavoured to take a favourable view of the opportunities for good which were before him. But he was

compelled to decline the offer. He realised that with all the responsibilities devolving on him he would be only in the position of a Treasury clerk, and the extent of his authority would depend on the whim of the Secretary. But even if those conditions could be satisfactorily arranged, Mr. CARRÈRE says that no man could combine the designing and superintendence, and the only feasible course will be to divide the work and entrust it to the best architects in the country, leaving the administrative portion only in the hands of the Government.

It is not always an advantage for an artist to have the name allotted to him which was borne by a greater artist. MALLARD TURNER, for example, has eclipsed WILLIAM TURNER. Yet the latter, who is further distinguished as "TURNER of Oxford," instead of having only a local reputation, would have been revered as one of the patriarchs of water-colour art if a namesake were not born fourteen years earlier in Maiden Lane, where the garbage of Covent Garden could develop his sense of colour. WILLIAM TURNER was born in 1789, in Blackbourton, Oxfordshire, and he was apprenticed to JOHN VARLEY. He exhibited as early as 1808 at the Water-Colour Society, and in the following year he was elected a member. But he cared little for fame if it had to be purchased by residence in London. WILLIAM TURNER returned to Oxford, and there he resided until his death in 1862. Views in the University town and in the country around formed his most characteristic works. Mr. RUSKIN reckoned him among his few favourites, for speaking of one of the old exhibitions in Pall Mall he said:—"Except the works of HUNT, PROUT, COX, FIELDING and FINCH, there are generally none in the room which deserve so honourable a place as those of WILLIAM TURNER." Through the enterprise of the President of Trinity College and Mr. T. W. JACKSON, of Worcester College, a loan exhibition of the artist's drawings is now open in the University Galleries, Oxford. It is a deserved tribute to the memory of a man who, under happier conditions, would have founded an Oxford school of painting.

AMONG the sights which every visitor to Scotland is expected to see, the two waterfalls of Foyers, and especially the lower one, hold a prominent place. They rarely disappoint anticipation, and all that was written about them in verse and prose appears to be without exaggeration. It is no wonder the proposal to utilise them for some new aluminium industry excites alarm among lovers of the picturesque. The promoters declare that the buildings which are to be erected will not diminish the beauty of the landscape, but as much has been said of every hideous railway station, viaduct or chimney which engineers have erected amidst the fairest spots in Britain. There is, however, no law to preserve landscapes from assaults or to secure the loveliness of nature. The local authorities have had to approve of the plans of the proposed works, although not without grumbling. Whether the Secretary of State for Scotland will be able to interfere before building operations are started remains to be seen, but as employment will be offered to a large number of men the Government are likely to hesitate in setting up an obstacle to a new industry.

THE second issue of the "Engineer's Year Book" has been published by Messrs. CROSBY LOCKWOOD & SON. It contains additional matter, and several of the articles, including "Girders and Bridges," have been rewritten. There is an astonishing amount of information in the pages, and of the kind which can be turned to account in everyday practice. We cannot mention the name of the publishers without expressing regret for the death of the head of the firm. Mr. CROSBY LOCKWOOD rendered many services to architecture and construction in general, not only by the publication of numerous excellent works, but also by his efforts to make technical literature available to students who were not wealthy. His name deserves to be recorded among the foremost diffusers of knowledge of the century.

MEMORIAL BUILDINGS, RAINHILL, HAYDOCK AND ASHTON-IN-MAKERFIELD, LANCASHIRE.

THESE buildings, views of which we publish to-day, have been erected at the sole cost of Miss RUTH EVANS, of Briars Hey, Rainhill, in memory of her brother, the late JOSEPH EVANS, colliery proprietor, of Haydock. The total cost of the combined schemes has been nearly 25,000*l.*, exclusive of land and furnishing.

The whole of the buildings have been carried out from the designs and under the superintendence of Mr. THOMAS W. CUBBON, architect, of Birkenhead, the contractors in each case being Messrs. HUGHES & STIRLING, of Liverpool, Mr. CLYDESDALE acting as clerk of works at Rainhill and Mr. HALSALL at Haydock.

Holt Buildings.

The Holt buildings consist of the following sections:—Congregational church providing seating accommodation on the ground-floor for about 650, having organ chamber, vestry and cloakroom accommodation at the rear. The style of the design is late Gothic in character, the plan of the church being cruciform, having chancel and transepts. The clerestory is carried upon handsomely-moulded arches, supported upon massive octagon pillars, having richly moulded caps and bases all of white Cefn stone, as are also chancel, transept and organ-chamber arches. One main front entrance and two side entrances are provided in addition to rear entrances. The buildings are faced externally with local red sandstone, and all the internal woodwork is of pitch-pine toned and varnished. The rostrum, which is of handsome design, is constructed of selected pitch-pine, the angle shafts being ebonised and other features richly moulded and carved. The traceried windows are filled in with enriched lead-lights of beautiful design. The gas-fittings, encaustic tiling, vestibule screens and decorative work have all been designed in harmony with the main structure. A handsome tower and spire occupies the south-west angle of main building, and rising as it does to an altitude of over 120 feet is seen for many miles on all sides.

Sunday school buildings, consisting of large assembly-hall capable of accommodating over 300 children and having in conjunction therewith four classrooms each for about eighteen scholars. These buildings, which are prominently situated at the right of church, are designed in harmony therewith, and have an octagon bell turret at the right of main gable, which is corbelled out and carried upon red granite shafts. The internal work is of similar material and character as the church, but somewhat less ornate.

Swimming and plunge bath, 50 feet in length and 23 feet wide, having the sides lined with white enamelled bricks, and the bottom laid with heavy white tiles on a concrete bed. Around the bath are fitted suitable dressing-boxes, and all modern conveniences are provided. The bath is lighted by a lantern roof, having movable louvred ventilator therein.

Gymnasium, clubhouse, cocoa-rooms, including large room 51 feet by 21 feet, having dressing-room and other conveniences attached. Two large reading-rooms on the first floor. Cocoa-rooms, consisting of large and beautifully fitted refreshment-room, having handsome serving bar, specially designed seats and tables. This section also includes commodious residence for manager, accommodation for bicyclists, &c.

Haydock Buildings.

These buildings consist of church to accommodate 650, similar in arrangement to the Rainhill Church, but are externally faced with red Ruabon brick, relieved by dressings of Runcorn red sandstone.

The school buildings consist of assembly hall for 300, having four classrooms and infants' room.

A handsome memorial drinking fountain has been erected in connection with these buildings by the residents in the neighbourhood.

The cost of these buildings was about 9,000*l.*

Ashton School Buildings.

These buildings have been erected for elementary education purposes, there being accommodation provided for about 850 children, and are two storeys in height.

On the ground floor there are infants' general school-room, juniors' classroom, babies' classroom, cookery classroom with scullery attached, joinery class with demonstration-room adjoining, boys' lavatory, infants' lavatory, two teachers'-rooms, caretaker's store, stationery store and marching corridor.

On the first floor are general mixed schoolroom, six large classrooms, girls' lavatory, head-master's room, stationery store and marching corridor.

A commodious covered playground is provided in the basement.

These buildings are faced with red Ruabon bricks having red sandstone dressings. The cost was about 5,200*l.*

The principal sub-contractors employed upon the works were as follows:—Engineering to swimming-bath and heating, Messrs. BRADFORD, of Salford; lead-lights and gas-fittings, Messrs. GREATRIX, of Manchester; plumbing, painting and glazing, Mr. R. ROBINSON, of Birkenhead; wrought-iron art work, Messrs. HARDMAN & POWELL, of Birmingham; gates and railings, &c., Messrs. MACFARLANE, of Glasgow; slating and plastering, Mr. MOORE, of Manchester.

MILTON ABBEY CHURCH, NEAR BLANDFORD.

THE ARCHITECTURAL ASSOCIATION.

AT the meeting of the Association on Friday evening last, Mr. Beresford Pite, vice-president, took the chair.

A vote of thanks was passed to Mr. E. A. Rüntz for inviting the members to inspect the new Pavilion Music Hall at Whitechapel.

Messrs. P. W. Meredith and J. W. Abraham were then elected members.

The Use of Sculptural Decoration at the Present Time.

Mr. STIRLING LEE opened the proceedings on the above subject by some remarks which chiefly referred to the sculptured panels which he had carried out on the exterior of St. George's Hall, Liverpool, which we have often before described.

Mr. F. T. W. GOLDSMITH, senior hon. sec, then read a communication from Mr. W. Young on the subject, in the course of which the writer said:—The subject of the use of sculpture in architecture is a most interesting one and one which I have done my best to promote, not only in talking and writing, but in actual work—because I believe in it. Sculpture in building has, in my opinion, been too much neglected, and ornament has been overdone. One would rather see in a building a small amount of really good sculpture than a large amount of ornamental work. At the same time one must not forget that sculpture on any great scale can only be done on public or monumental buildings; in domestic work it is not likely to hold a large place. I think it is the office of the architect to produce sculpture in place of ornament whenever he has the opportunity, or rather he should try and make the opportunity. The question of cost is undoubtedly a difficult one to overcome, but I think if we, when the opportunity of using sculpture occurs, put clearly and forcibly before our clients the difference in result and value between sculpture and ornament, this difficulty may be overcome; at least, such has been my experience. But, granted the opportunity to employ sculpture, which is the grandest decorative aid to architectural design, we must take care that it is not merely figure-carving in stone but sculpture of the highest class which we must aim at. In my opinion, sculpture in architectural work brings out the highest qualities of the artist. There he deals with its conception, with its composition, with its proportions, without going into the elaboration of too much detail. For sculpture in architecture should, first of all, be broad and very simple. It is also necessary that it should be to a scale, both in size and relief, proportionate to the place in the building which it occupies. One has seen in many of the recent efforts to adopt sculpture in buildings, figures of such a small size and so out of proportion to surrounding work that they look like toy figures only fit for the Lowther Arcade, and forming no part of the architectural scheme. Not only should the scale be proportionate to the building, but it should not be any random figure stuck in in any place, but the whole should be part of a scheme both in subject, in size, in treatment and in relief, so as to form a harmonious part of the building which the sculpture decorates. I am afraid that in the present day, with a growing tendency to produce sculpture in buildings, we shall get, as we have in other things, a cheap and shoddy sculpture. If we employ sculpture at all we should take care that it is of the very best. It should be sculptor's sculpture, and not stone-mason's sculpture. I had an example of this a little time ago, when a man was introduced to me who offered to execute a

7-foot statue in stone for one of my buildings for something like 30*l*. I happened to have seen some of the man's work, and in reply, while thanking him for his kind offer, I remarked to my friend standing beside me, who said, "Very reasonable price," "Yes, but I would rather pay 50*l*. not to have his sculpture in my building than pay 30*l*. and have it." My advice to you is, avoid this kind of sculpture, as well as all pretence at sham art. If you cannot get the real article do without it.

Mr. F. W. POMEROY next read a paper on "Plaster Work." After a few preliminary remarks, Mr. Pomeroy said:—The material known as plaster-of-Paris is the basis of nearly all work I shall consider this evening, and is used by sculptors and others for taking casts, &c. It was well known to the ancients, who obtained from Syria, and probably other countries, a stone called by Theophrastus "gypsos," which resembled alabaster, and was converted into plaster by burning in a suitable furnace, grinding and sifting. If one part of plaster is mixed with about 2½ parts water, after a time it sets into a hard and enduring mass. It was employed in the same way and for similar purposes as at the present day. One of the most important deposits is that of Montmartre, Paris, but it is also found abundantly in Derbyshire in this country, and many other parts of Europe and America. The purer semi-transparent specimen of gypsum or alabaster is used for ornamental work, such as fine masonry and statuary, and is a very durable and beautiful material for interior work. By adding a little lime to plaster-of-Paris, it causes it to set slower but increases its hardness. Substances other than lime are also employed for the purpose of rendering the mass hard; thus Parian cement consists of fine plaster mixed with alum and borax, and re-burning.

A cement used by marble masons is made of the same plaster mixed with a small quantity of alum and soda. For building work, a first coat is generally laid on of lime thoroughly slacked (so as to be free from all tendency to contract moisture) and mixed with sand and cow hair.

The face of this coat (which should be of considerable thickness) is trowelled or indented with cross lines to form a key for the finished coverings. The second coat is applied when the first is thoroughly dry. (This is a necessary precaution, or the damp will work through and destroy or discolour any decoration that may be applied.) It is then rubbed with a flat board or float, so as to fill the indentations and cover the surface equally. The ornamental or finer plaster-of-Paris is then applied before the second coat is quite dry.

Many architects desire that their ornament should be modelled *in situ*, and I am fully aware of the importance of this; but have always found that it is quite impossible under the present conditions of building to carry out entirely a design of an elaborate nature, such as figure-work or intricate foliage; a simple design is possible only, and the plan generally adopted is to model in clay or wax a piece sufficiently large to form an idea of the scale and projection of the modelling, and fix it up in something like the position it will eventually occupy. As a ceiling is generally lighted from windows that come underneath, a good way of testing the effect is to lay the model flat on the floor and hold a good-sized looking-glass as high as necessary above it; by this means one can get a good general idea of the effect of the whole.

But reflected lights and other reasons demand that the work should always be considered in a liquid state, *i.e.* to be worked on and completed after it is fixed. This may be said to apply to all architectural decoration.

Where the windows run up close to the ceiling I have found flat or low relief most agreeable, and very high relief is never desirable; it harbours dirt and dust and throws shadows, which become very troublesome to the people who have to live in the rooms.

The charm of much of the old ceiling-work, I venture to think, is enhanced by the many coats of paint or whitewash they have received, which has stopped up the small cracks in the work and accidentally given breadth to the whole, and much modern work would be improved by the same treatment.

I have tried in ceiling-work that I have been engaged on lately to avoid sharp undercutting, and where undercutting is necessary to give accent to the design, it should be done with a rounded instead of a sharp edge, and a much softer shadow is thus obtained. But as each fresh work is a new problem, so the modeller, to have the true decorative spirit, must constantly bear in mind the general scheme of the mouldings that surround his work and govern the scale, and perhaps the most noticeable feature in modern surface decoration is overcrowding, and one of the greatest difficulties of the designer is to know how much to leave out rather than what to put in. Indeed, the designer who understands this quality has got well through his troubles, and the value of an occasional plain space cannot be over-estimated.

Of course, the well-trained figure sculptor understands the value of tone, light and shade, and envelopment, but unfortunately the common or everyday carver has little or no time

allowed to consider such abstruse problems, consequently his only idea is to make the particular piece of work that he is engaged on "sing out," without any regard to the *ensemble*.

For repeating ornamental plaster models, gelatine, wax and piece moulding in plaster are the methods usually employed. Gelatine is the simplest and best when only a few casts are required, as it can be done without any complications in the case of undercutting. I have here a small example of the gelatine mould process of casting (which may interest some of you after I have finished this paper). Wax moulds are generally used for the so-called fibrous or canvas casts of commerce, as the canvas in the plaster holds the moisture too long and destroys the face of the gelatine.

Piece moulding is a more complicated way of obtaining reproductions, and is used by moulders who may desire to preserve their moulds for future occasion. The object to be cast is covered by a number of small pieces of plaster, the edges of which are trimmed with a knife, so that they will each draw freely, and moistened with a little sweet oil and soap mixed, to prevent sticking together; when the object is completely enveloped by a number of pieces, it is necessary to hold them together by means of a case, also made of plaster. The liquid mass is then poured in slowly, and the mould turned, so that it may be covered equally. When set the outer case is removed, and then each piece carefully drawn away from the reproduction and replaced in the case. The thin seams which one sees on the plaster-casts are caused by these joints in the piece mould. For work executed *in situ* a mixture of Parian cement, well burnt slacked lime, putty and silver sand, the proportions varying for different kinds of work, but generally about two parts Parian cement to one of sand and one lime, but this is more properly stucco-duro, and a ground of Portland cement and common hair mortar is used, the Portland cement stopping the suction and allowing the applied stucco to set more slowly.

Stucco-duro, as practised by the Italians, is a very ancient method, and is mentioned by Vitruvius. It was almost lost, but was revived again in Italy in the sixteenth century.

Raphael and Giovanni da Udine were then so interested by the discoveries during the exhumation of the Baths of Titus, under Leo X., that they at once made experiments in this material, and the Loggia of the Vatican was one of the first results. It was composed of plaster-of-Paris, silver sand and marble dust, and was capable of taking a high polish. In Kensington Museum there is a beautiful model of the central hall of the Villa Madama in Rome, which was decorated by Giulio Romano and Giovanni da Udine. The model also exemplifies the possibilities of this composition, for its maker, Professor Mariani, of Perugia, has employed stucco-duro for the modelling of the ornament, which shows it can be used for the finest work; indeed, it is used by modellers for goldsmith's work as less liable to injury than wax. If used too quickly and heavily it will crack, but it must be modelled rapidly and surely, and only those of great dexterity need attempt it.

A stucco composed of plaster and glue-water is used by modern sculptors, and is preferred to clay for very large work. Mr. Watts modelled his great statue of Hugh Lupus for Eaton Hall in it, and the groups in front of the Trocadéro in Paris by Falguière were modelled in the same material.

You first make a sketch model in clay or wax to scale, taking great care to have your proportions exact; then the large framework is made of iron supports and wood covering, and a rough coat is laid on. After this the work is modelled in the stucco. Finish can be obtained by using flat brushes. It has a very loose and pleasant surface if done properly.

Stucco-work was much employed on the palace of Nonsuch, built by Henry VIII. It was executed by artists brought from Italy, but every trace of this palace has disappeared; but the men left their influence, and stucco was employed to decorate houses until the end of the reign of Charles II., when it began to decline.

Graffito, or sgraffito, is another way of decorating by means of prepared plaster grounds, cutting away or scratching through the upper surface, and revealing in parts a background of a different colour.

The first coat is made of sharp sand and Portland cement; the second coat is usually coloured with Indian red, yellow ochre, or manganese black. About one part of prepared distemper colour to one and a half of Portland cement is the proportion for this. Then a final coating of selenitic cement and silver sand carefully mixed together is laid on very thinly, not thicker than one-sixteenth of an inch, before the second coat is quite dry. Then the cartoon, having been prepared, is placed on the surface, and the outline firmly pricked and pounced, the cartoon removed and the design cut into the surface of the second coat, which is done with a steel scraper. Parian cement may be used instead of selenitic if the outer coating is desired white.

Care must be taken in cutting, which should be with slanting edges, which gives roundness and softness to the finished work. A good draughtsman will have little trouble in learning

this kind of work, and it should commend itself to architects for its durability.

Gesso is yet another way of using plaster, but this more properly belongs to the painter's art, and is most successful when confined to very low relief work, as for the decoration of frames, caskets, panels of cabinets, &c. There are many kinds of gesso, and fine examples may be seen in Kensington Museum. For bold work plaster-of-Paris and thin glue or size-water, a little tow pulled thin and steeped in the stuff is used for building up your projections; a few flat-headed copper nails are useful if they can be driven into the background to prevent the work lifting. This should really be applied to a wood or fibrous plaster background, and it is always necessary to stop suction by painting the ground over with a coating of thin shellac.

For fine work, laid on with a brush, glass is good for backgrounds; you can lay it over the design and copy through the glass. The liquid, which must be used hot, is composed of whiting previously soaked in water and mixed with linseed oil, and a little resin added.

The proportions vary, but it can be made very easily, and a few experiments will insure success. A pot of hot water should be kept handy to clean your brushes as the stuff cools. I have used, on the recommendation of Mr. Walter Crane, a very good stuff called "Denoline," sold by most colourmen. This is a fine powder done up in 1s. boxes, and is used by mixing with cold water only. You may make it stiff or liquid, as you require it. It sets hard but slowly, and sticks fast—great virtues in gesso. Whiting and parchment size is the gesso used by frame-makers; ordinary house-painter's putty worked up with whiting, oil and water, is also used for scrolls, &c. Carton pierre is a material much used in France, but I have had no experience with it.

I was told of a method employed by an American artist, which struck me as being very ingenious. He had his gesso prepared and put up in leaden tubes, similar to those used for oil colours. Then, preparing his background by tracing the design slightly on it, he squeezes the gesso on and flattens such parts that require it with an ivory or steel tool. For mere line design this way is admirable; works are done with great rapidity, much quicker than would be possible with a brush.

There are many processes for hardening plaster-of-Paris; one way is to dissolve a quarter of an ounce of soft soap in a pint of water, and an equal quantity of white wax is afterwards incorporated.

The cast is dipped in this liquid, or, if a surface of any dimensions, the mixture is laid on with a soft brush. After drying about a week, it may be polished with soft rag and French chalk.

Linseed-oil and wax is used by some, but this turns very dark in time and in places where hidden from the light it will become almost black.

Another way is to give the plaster a thin coating of white shellac, then paint over this a good coating of boiled soft soap and polishing when dry with a rag. This is useful for stopping the porous surface of the plaster, but it must be perfectly dry before the coating is applied. I am told a Mrs. Laxton Clark invented a means of hardening plaster, but I think all modellers would prefer putting their work in a more durable material.

The tools and materials required for gesso, stucco and similar work can be easily obtained at various oil and colour warehouses in London. I have found that a child's rubber ball cut in half is an excellent vessel for mixing small quantities in; it can be cleaned easily by merely turning inside out, and does not break; a few basins, a glue-pot, some iron plaster-spoons and some small steel spatulas are also useful.

I have endeavoured in as brief a manner as possible to explain some of the most important uses of plaster for decorative purposes; but to become thoroughly acquainted with any particular work the student should spend a short time in the workshops, for the secret lies not in the tools or materials, but in the hand and brain of the worker.

Mr. H. H. STATHAM proposed a vote of thanks to Mr. Lee and Mr. Pomeroy, which was seconded by Mr. W. D. CAROE and carried by acclamation.

PLANNING AND FITTING SCHOOLS.

THE code of regulations for day schools issued by the Education Department contains several alterations relating to the buildings, especially in rules 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 13, 14, 15, 16 and 17. The following is a reprint of the Schedule VII. in its latest form:—

Article 85 (a) of the code provides as follows:—"All new school premises and enlargements must conform generally to the rules contained in Schedule VII., and the plans must be approved by the Department before such new premises and enlargements are passed under this article."

RULES TO BE OBSERVED IN PLANNING AND FITTING-UP PUBLIC ELEMENTARY SCHOOLS.

School planning is the science of thoroughly adapting every part of a building, even the minutest detail, to the work of school teaching. Convenience of plan, suitable lighting, proper subdivision into classes and thorough ventilation, with warmth but without draughts, are its leading essentials. Attention to small points is of extreme importance. Sanitary laws are here as vital as in a hospital. The school-architect is recommended first to perfect his plan. His own skill should then enable him to clothe it with form, proportion, character and colour.

These building rules are intended to assist school managers, school boards and their architects to produce the most compact, convenient and economical plans of school buildings.

The annual cost of maintenance should be kept in view as much as the capital expense.

It is desirable that, before instructing an architect, the teaching staff of a school should be well considered, so that the number of rooms and the accommodation of each may be approximately settled before the expense of building is incurred.

REQUIREMENTS.

School boards and school promoters are requested to note that the Education Department require the following plans, and that inattention to such requirement entails delay:—

I. A block plan of the site, drawn to a scale of 20 feet to an inch. This plan must indicate:—

(a) The position of the school buildings. (b) Outbuildings. (c) Playground. (d) Drains (collateral and main), with their fall and depth below ground. (e) Entrances. (f) Boundary walls, or fences, and their nature. (g) Roads. (h) The points of the compass. (i) The levels of the ground at the principal points.

II. A plan of each floor of the schoolrooms (and teacher's or caretaker's residence, if any), drawn to a scale of 8 feet to an inch. The internal fittings of the rooms (fireplaces, groups of desks, benches, &c.) must be accurately shown. The plan should also state whether the rooms are intended for boys, girls or infants. In cases of enlargement, a plan showing the buildings as they exist is needed.

III. Sections and at least four elevations, also drawn to a scale of 8 feet to an inch. The ceiling, the positions of window-heads in relation thereto and the mode of ventilation must be shown.

N.B.—(a) Pencil drawings cannot be received, but coloured tracings in ink may be submitted while plans are in the preliminary stage of pencil, so that suggested alterations can be adopted without difficulty or expense. (b) Diagrams are of no value and cannot be accepted. (c) In the case of enlargements, the whole site and the existing building should be accurately shown. (d) All plans should be dated, the scales drawn on and dimensions figured.

IV. A detailed specification separated under the several branches of the building trade.

BUILDING RULES.

1. Planning and Accommodation.

1. In planning a school the first thing is to seat the children in the best manner for being taught. The accommodation of each room depends not merely on its area but also on its shape (especially in relation to the kind of desk proposed), the positions of the doors and fireplaces, and its proper lighting. The second point is to group the rooms together in a compact and convenient manner.

2 and 3. Schoolrooms.

2. Every school must have a schoolroom as hereunder or a central hall as under rule 8. The proper width for a schoolroom is from 18 to 22 feet. In a room 18 feet wide groups of long desks, three deep, should be used; where four rows are used the width should be 21 feet 6 inches, and if the width is 22 feet, dual desks, five rows deep, are most suitable. (For classrooms, see rule 7.)

(a) Accommodation in schoolrooms for elder children is calculated by the number of children seated at desks and benches, subject to a minimum of 10 square feet per child being provided. For the mode of calculating accommodation in classrooms see rule 7, in infant schools see rule 16 (f).

(b) Double bank schools (now almost obsolete) require rooms 32 feet wide, walls left clear for three rows of desks, and ample lighting from windows on both sides extending to ceiling.

(c) Wasted space cannot be considered.

3. The doors and fireplaces in schoolrooms must be so placed as to allow of the whole of one side of the schoolroom being left free for the groups of benches and desks.

(a) No schoolroom lighted from one side only can be approved. The gable ends should be fully utilised for windows (see also rules 9 and 9 (b).)

4. Walls, Floors and Roofs.

4. The walls of every schoolroom and classroom, if ceiled at the level of the wall-plate, must be at least 12 feet high from the level of the floor to the ceiling, and, if the area contain more than 360 superficial square feet, 13 feet, and, if more than 600, then 14 feet.

(a) The walls of every schoolroom and classroom, if ceiled to the rafters and collar-beam, must be at least 11 feet high from the floor to the wall-plate, and at least 14 feet to the ceiling across the collar-beam.

(b) Great care should be taken to render the roofs impervious to cold and heat.

(c) Roofs open to the apex are not approved. They can only be permitted where the roofs are specially impervious to heat and cold, and where apex ventilation is provided. Iron tie-rods are least unsightly when placed horizontally.

(d) The whole of the external walls of the school and residence must be solid. If of brick, the thickness must be at least one brick and a half, and if of stone, at least 20 inches.

(e) All walls, not excepting fence walls, should have a damp-proof course just above the ground line.

(f) The vegetable soil within the area of the building should be removed, the whole space covered by a layer of concrete not less than 6 inches thick, and air bricks inserted in opposite walls to insure a through current of air under floors for ventilation to joists.

(g) Timber should be protected from mortar and cement by asphalt or tar.

5. Entrances.

5. Entrances should be separate for each department. In large schools more than one entrance to each department is desirable (see also rule 10). The principal entrances should never be through the cloak-room. Entrance doors should open outwards as well as inwards. A porch should be external to the schoolroom.

6. Cloak-rooms and Lavatories.

6. Cloak-rooms must be external to schoolrooms and classrooms, with gangways at least 4 feet wide, amply lighted from the end. Hat-pegs should be 12 inches apart, numbered and of two tiers. The hanging-space necessary to provide a separate peg for each child is thus 6 inches lineal.

Thorough ventilation is essential, so that smells are not carried into the school.

Lavatory basins are needed (see rule 13 (h)). The girls' schools require a larger number than boys' or infants'.

A lock-up slop-sink, water-tap and cupboard are desirable for the caretaker.

7. Classrooms.

7. Classrooms are calculated at 10 square feet if not providing accommodation for more than sixty children. Six rows of dual desks or four rows of long-length desks are permissible in such classrooms. When the front of a class is narrowed, but the area of the room is not reduced, a seventh row of dual desks or a fifth row of long desks may be allowed. Rule 2 applies to all rooms providing accommodation for more than sixty, or being more than 24 feet 8 inches deep from the window wall.

(a) The minimum size of classroom is 18 feet by 15 feet. If desks are placed longitudinally the width should not be less than 16 feet. This latter width is also allowed in schoolrooms of very small size.

(b) The classrooms should never be passage-rooms from one part of the building to another nor from the schoolroom to the playground or yard, and should be on the same level as the schoolroom. Each should be easily cleared without disturbance to any other room. Doors should open both ways.

(c) The number of classrooms should, where practicable, equal the number of classes in the schoolroom; usually five classrooms are necessary for the six standards.

(a) The excessive use of movable partitions should be avoided.

8. Halls.

8. Large schools are sometimes planned with a central hall, from which the classrooms are entered, and which is not as a rule calculated in the accommodation.

In the case of mixed schools an exception is made, one class being necessary in the hall in order to secure a teacher's supervision of the separate exits to the latrines (see rule 13 (a)); the hall must therefore be suitable for teaching such class. It must be fully lighted, warmed and ventilated, and must contain a floor space of not less than 1,200 square feet, and the position of the class should be marked on the plan. Halls of excessive size are not approved.

9. Windows.

9. Every part and corner of a school should be fully lighted. The light should, as far as possible, and especially in classrooms, be admitted from the left side of the scholars. [This

rule will be found greatly to influence the planning (see rules 3 (a), 9 (b) and 11 (a)). All other windows in classrooms should be regarded as supplementary or for summer ventilation. Where left light is impossible, right light is next best. Windows full in the eyes of teachers or scholars are not approved. In rooms 14 feet high any space beyond 24 feet from the window wall is insufficiently lighted.

(a) Windows should never be provided for the sake merely of external effect. All kinds of glazing which diminish the light and are troublesome to keep clean and in repair should be avoided. A large portion of each window should be made to open for ventilation and for cleaning.

(b) The sills of the main lighting windows should be placed about 4 feet above the floor, and the tops of some should reach nearly to the ceiling with a portion made to swing. The ordinary rules respecting hospitals should here be remembered. Large spaces between the window heads and the ceiling are productive of foul rooms.

(c) Skylights are objectionable and should never be resorted to where windows are possible. Plans needlessly involving their use cannot be approved, except in the case of central halls having ridge, or apex, ventilation.

10. Staircases.

10. A staircase like a porch must be external to the schoolroom. No triangular steps or "winders" should be used. Each step should be about 13 inches broad and not more than 5½ to 6 inches high. The flights should be short and the landings unbroken by steps. The number of staircases should be sufficient, not only for daily use, but also for rapid exit in case of fire or panic.

11. Ventilation.

11. Apart from open windows and doors, there should be provision for copious inlet of fresh air; also for outlet of foul air at the highest point of the room; the best way of providing the latter is to build to each room a separate air chimney carried up in the same stack with smoke flues. An outlet should have motive power by heat or exhaust, otherwise it will frequently act as a cold inlet. The principal point in all ventilation is to prevent stagnant air. Particular expedients are only subsidiary to this main direction. Inlets should provide a minimum of 2½ square inches per child, and outlets a minimum of 2 inches. Rooms should, in addition, be flushed with fresh air from windows about every two hours.

A sunny aspect is especially valuable for children and important in its effects on ventilation and health.

(a) Although lighting from the left hand is considered so important, ventilation in summer demands also the provision of a small swing window as far from the lighting as possible and near the ceiling.

12. Warming.

12. The warming should be moderate and evenly distributed so as to maintain a temperature of from 56 deg. to 60 deg. When a corridor or lobby is warmed the rooms are more easily dealt with and are less liable to cold draughts. Where schools are wholly warmed by hot water the principle of direct radiation is recommended. In such cases open grates in addition are useful for extra warming occasionally and their flues for ventilation always.

(a) A common stove, with a pipe through the wall or roof, can under no circumstances be allowed. Stoves are only approved when (i.) provided with proper chimneys (as in the case of open fires); (ii.) of such a pattern that they cannot become red-hot or otherwise contaminate the air; (iii.) supplied with fresh air direct from the outside by a flue of not less than 72 inches superficial; and (iv.) not of such a size or shape as to interfere with the floor space necessary for teaching purposes.

(b) A thermometer should always be kept hung up in a school.

13. Sanitary Arrangements.

13. Water-closets within the main school building are not desirable, and are only sanctioned for women teachers. All others should be at a short distance and completely disconnected from the school. Privies should be fully 20 feet distant.

(a) The doors, staircases and passages leading from the schoolroom to the latrines (whether in mixed or in other schools), and the latrines themselves, must be separate for the two sexes, and constructed entirely apart from each other. In the case of a mixed school this rule especially affects the planning. Where passages or corridors are unavoidably used by both sexes, there must be complete supervision from the classrooms by sheets of clear glass.

(b) Each closet must be not less than 2 feet 3 inches wide nor more than 3 feet, fully lighted and ventilated and properly screened or supplied with a door. More than one seat is not allowed in any closet.

(c) The children must not be obliged to pass in front of the teacher's residence in order to reach their latrines.

(d) The following table shows approximately the number of closets needed:—

	For Girls.	For Boys.	For Infants.
Under 30 children	2	1	2
" 50 "	3	2	3
" 70 "	4	2	3
" 100 "	5	3	4
" 150 "	6	3	5
" 200 "	7	4	6
" 300 "	8	5	7

Urinals in proportion.

(e) Cesspits and privies should only be used where unavoidable, and should be at a distance of at least 20 feet from the school. (Building form "A," which may be obtained on application, gives suggestions as to their construction and arrangement.) Earth or ash-closets of an approved type may be employed in rural districts, but drains for the disposal of slop and surface water are still necessary. The proximity of drinking-wells should be carefully avoided.

(f) Soil-drains must always be laid outside the building (on a hard, even bottom or concrete) in straight lines with glazed stoneware pipes, carefully jointed in cement and made absolutely water-tight. A diameter of 4 inches is sufficient unless for drains receiving the discharge of more than ten closets. Above this number the diameter should be 6 inches. The fall should never be less than 1 in 30 for 4-inch, and 1 in 40 for 6-inch drains. An inspection opening or chamber should be provided at each change of direction, so as to facilitate cleansing the drain without opening the ground. Every soil-drain must be disconnected from the main sewer by a properly constructed trap placed on the line of drain between the latrines and the public sewer. This trap must be thoroughly ventilated by at least two untrapped openings, one being the 4-inch soil-pipe carried up full size above the roof and the other an inlet pipe connected with the side of the trap furthest from the public sewer. Automatic flushing tanks are desirable where trough closets are used.

(g) Urinals must in all cases have a sufficient supply of water for flushing.

(h) Waste pipes from sinks or lavatories should be first trapped inside and then made to discharge direct through the wall over a trapped gully.

14. Desks.

14. Benches and desks, graduated according to the ages of the children, should be provided for all the scholars, and placed at right angles to the light (see also rules 3 (a) and 9).

An allowance of 18 inches per scholar at each desk and bench will suffice (except in the case of the dual desk), and the length of each group should therefore be some multiple of 18 inches, with gangways of 18 inches between the groups and at the walls. In the case of the dual desk the usual length is 3 feet 4 inches and the gangways 1 foot 4 inches.

(a) The desks should be very slightly inclined. An angle of 15 deg. is sufficient. The objections to the inclined desk are that pencils, pens, &c., are constantly slipping from it, and that it cannot be conveniently used as a table. The objection to the flat desk is that it has a tendency to make the children stoop. A raised ledge in front of a desk interferes with the arm in writing.

(b) No benches and desks should be more than 12 feet long. And no group of long desks, in a schoolroom providing for more than 60 children, should contain more than four rows of benches and desks, or three if the width is less than 21 feet 6 inches (rule 2), because in proportion as the depth is increased the teacher must raise his voice to a higher pitch; and this becomes exhausting to himself, while at the same time it adds inconveniently to the general noise.

(c) With the use of the dual desk the space between seat and desk disappears, as the children stand in the gangways.

15. Sites and Playgrounds.

15. Every school should have an open airy playground proportioned to the size and needs of the school. The minimum size of site is, in the absence of exceptional circumstances, a quarter of an acre for every 250 children. If the school is of more than one storey this area may be proportionally reduced. The minimum open space is 30 square feet per child.

(a) In the case of a mixed school, playgrounds must be separate for the boys and girls.

(b) All playgrounds should be properly levelled, drained, enclosed and fitted with some simple appliances. A portion should be covered, having one side against a wall. A covered way should never connect the offices with the main building. Buttresses and corners should be avoided.

(c) An infant school should have its playground on the same level as the school, and open to the sunshine.

16. Infant Schools.

16. Infants should not, except in very small schools, be taught in the same room with older children, as the noise and the training of the infants disturb and injuriously affect the discipline and instruction of the other children.

(a) There must be no opening wider than an ordinary doorway between an infants' and any other schoolroom, because of the sound of the infant teaching.

(b) An infant school (and playground) should always be on the ground floor, and if more than 80 scholars are admitted, should have one gallery and a small group of desks for the occasional use of the older infants.

(c) No infant gallery should hold more than eighty or ninety infants. It should be well lighted from one side. The light for object lessons is as good from the right as from the left.

(d) The width of an infant schoolroom should be in proportion to its size, but not more than 24 feet. A covered marching-ground is desirable.

(e) The babies' room should always have an open fire, and be maintained at a temperature of about 65 deg. As a rule it should not contain more than fifty children. Large schools may require two communicating rooms for babies, one fitted with low Kindergarten desks, the other providing ample floor space for exercises.

(f) The accommodation of an infant school is calculated at 8 square feet for each child, after deducting wasted or useless space, but a larger area should be allowed wherever practicable. Care should be taken that the numbers are conveniently seated and that space is left for marching. Where a second standard is taught in an infant school the accommodation for it is calculated at 10 square feet per child.

17. Cookery Centres and Classrooms.

17. A cookery centre should be capable of accommodating at least one class of eighteen at practice and not more than fifty-four at demonstration at one time. It should be approached by a separate entrance. A small scullery is necessary and also a bonnet-room. A cookery classroom should contain at least 400 superficial feet, and be so placed that smells from it cannot pervade the other rooms of the school.

18. Workshops and Laundries.

18. Workshops and laundries are best entirely apart from the school.

19. Teacher's House, &c.

19. The residence for the master or mistress should contain a parlour, a kitchen, a scullery and three bedrooms; and the smallest dimensions which their Lordships can approve are:—

For the parlour	12 ft. by 12 ft.	of	8 ft. }	in height to wall
For the kitchen	12 ft. by 10 ft.	super-	8 ft. }	plate.
For one of the bedrooms	12 ft. by 10 ft.	ficial	8 ft. }	if ceiled at wall
For two other bedrooms	9 ft. by 8 ft.	area ;	plate, or 7 ft. to wall	plate and 9 ft. to ceiling

(a) The residence must be so planned that the staircase is immediately accessible from an entrance lobby and from the parlour, kitchen and each bedroom, without making a passage of any room.

(b) Each bedroom must be on the upper storey, and must have a fireplace.

(c) The parlour must not open directly into the kitchen or scullery.

(d) There must be no internal communication between the residence and the school.

(e) Windows should be carried up as nearly to the ceilings as practicable.

(f) There must be a separate and distinct yard, with offices.

(g) A caretaker's house need not be quite so large.

(h) All houses should be separate from and not built as part of the school-house.

20 and 21. Loans.

20. No loan of money can be obtained from the Public Works Loan Commissioners unless the whole cost of the school, exclusive of site, legal expenses, extra rooms for instruction authorised by the code, and residences (if any), is kept within the sum of 10*l.* per child accommodated. An allowance will also be made in reference to the cost of a central hall not calculated in the accommodation (rule 8). Rooms for extra subjects recognised by the new code, such as drawing, chemistry, &c., will have an allowance varying from 15*s.* to 20*s.* per square foot. From 275*l.* to 400*l.* will be allowed for a caretaker's house. From 275*l.* to 500*l.* will be allowed for a cookery centre. Whether the necessary loan be borrowed in the open market or not, extravagant plans cannot be approved.

21. The Department do not entertain applications for loans when the expenditure has been incurred without their previous sanction.

Correspondence

Simplicity in Architecture.

SIR,—It was my privilege to attend the meeting at the Institute of Architects, when the several papers under the above heading were read—one by the learned President, and two others by accomplished architects not at present members of the Institute. The subject was an attractive one, and on speculating beforehand what its treatment might be, one had imagined the walls of the Institute hung with drawings of ancient architecture illustrating the spirit of simplicity of treatment, and one had thought of seeing in artistic form something perhaps

from Durham, Lincoln, Southwell, Gloucester, Tewkesbury, Winchester, Norwich, Peterborough or Ely; or, perchance, from some of the early and therefore simple abbey churches which abound throughout the land. Or otherwise one had thoughts of a selection from the many ancient parish churches or domestic buildings which display this excellent quality of simplicity to the utmost. Prior to the meeting, two hours (not warm ones on that bitter day) spent in the church of St. Saviour's, Southwark, suggested to one that perhaps that building, with its ample solids, nicely-proportioned parts and refined details, might in the evening furnish an example of true architectural simplicity (by the way, it is to be hoped that precious bit of untouched arcading at the south-west angle of the church will never have hand laid on it); but the papers took quite another line, and those present at the meeting had the pleasure of seeing what was provided as good

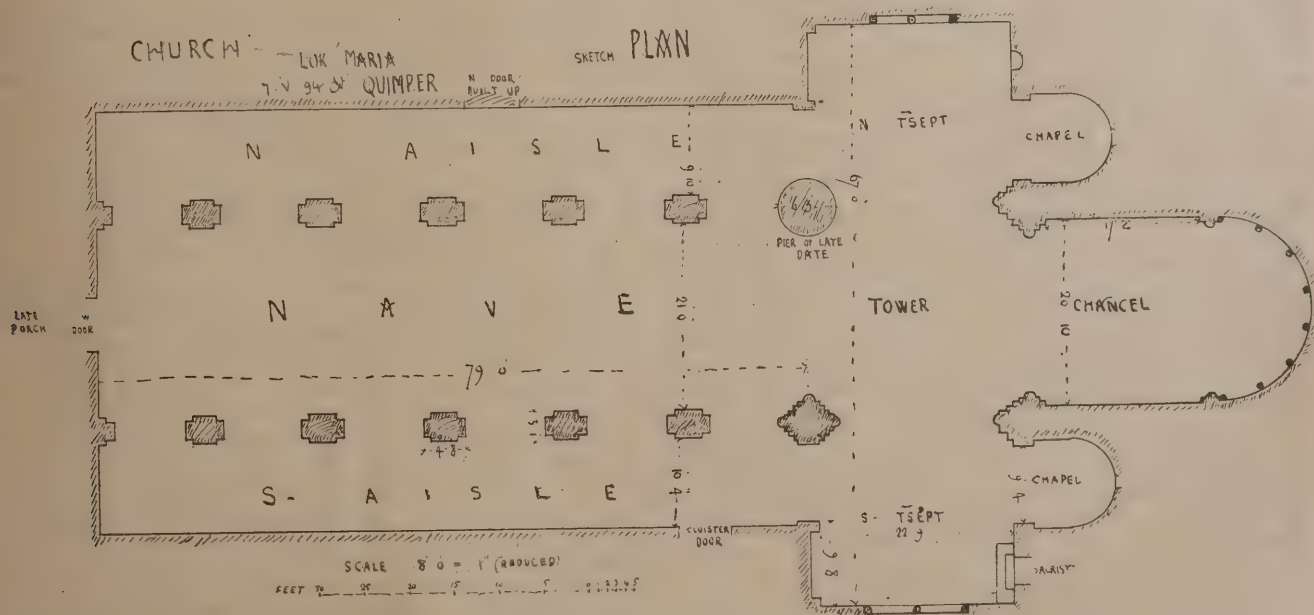

INTERIOR OF LOK MARIA, QUIMPER.

examples in illustration of the text. Mr. Halsey Ricardo showed a good sketch of a modelled "cherub's" head (*face* Welby Pugin), and in contrast with it a drawing of a hideous familiar advertisement; but in what way this concerned the subject of "simplicity in architecture" was somewhat of a puzzle to a stranger from the country, and the worst of it was that in order to give effect to this forcible contrast, the Della Robbia head was torn down at an early stage, and the wretched grotesque stared impudently at the assembly of

last year it was my delight to travel in France, Normandy and Brittany, seeing Dieppe, Rouen, Coutance, Léon, Dol, Mont St. Michel, Dinan, Lannion, Treguier, Morlais, Lamballe, Quimper, Auray, Carnac, Vannes and Chartres. Truly an architectural feast. Every day a festival. Amongst all these glories there was much of course which did not display true simplicity in the art; but, oddly enough, the subjects which did most forcibly express this great quality made most impression on one's memories. The mighty alignments of the great

LOK MARIA, QUIMPER.

artists the whole evening. If one might attempt a joke, one would like to whisper in the ear of the exhibitor, "What politeness did the advertiser send to your breakfast-table next morning?" But my intention was not to comment on the meeting at the Institute, much less on the papers read—that would be unbecoming; but it occurred to me at the time that a fitting illustration of "simplicity in architecture" might be sent to you from a sketch made last summer of a small yet interesting subject. For three weeks in the cold month of May in

monoliths at Kermario are a most impressive work, but this, of course, is too archaeological for Institute consideration. Yet one thinks monuments such as these (rude in the extreme though they be) need not be boycotted by the architect even in these elaborate "terra-cotta" days, for in truth they bring about what Professor Ruskin years ago said must take effect if architecture is "to tell"—they make an irresistible thrust to the heart. Then, again, La Crypte de l'Aquilon at Mont St. Michel, the aisles of the cathedral of Le Man and the

church on the hill at Lannion, the market hall at Auray and the early church of Lok Maria at Quimper may be cited as true examples of simplicity in architectural art. Quimper is full of Mediæval work, early and late, yet having once caught sight of its early church, all else for me gave way to its attractions. Its nave is very like the original nave at Bakewell, in Derbyshire. Alas! only the western bay there now remains. Thus I am able to send you in rough form what seems to me to be an excellent example of true simplicity in architecture—in plan, section and design. But it may be asked, is this the sort of thing to be held up as simplicity of treatment in these progressive days of easily-produced machine-made cast enrichments and elaborations? Well, on the one hand we have the simple innocence of the dutiful execution of the architect's own handiwork, together with perfect truth of construction, and on the other a mechanical multiplied reproduction from models not of the architect's own modelling. Each designer must make his choice in what direction he will employ his talents, but assuredly true "simplicity in architecture" cannot come of machine-made ornament, however profusely employed.

February 28, 1895.

C. LYNAM.

Specialties in Bills of Quantities.

SIR,—May I through your columns be allowed to draw the attention of architects and engineers to the following practice which appears to be growing, and the result of which, in many instances, is of a detrimental nature?

An architect having a building to erect issues bills of quantities, which certain contractors apply for and tender on. In these quantities the architect, through experience, specifies certain articles which are sometimes of higher price than goods of a more or less similar quality. Probably the larger number of contractors tendering make up their tenders on prices of the special material specified. The remaining two or three contractors use another method, viz. instead of the article specified they, knowing some manufacturer who offers to supply an article sufficiently good, fill in their quantities with the price of his manufacture, which may be some 5 per cent. or 10 per cent cheaper, they intending, if their tender is accepted, to get the architect's permission to change the specification. The foregoing naturally applies more to a mason's work in a building than to the later contracts; the result of which, in a 10,000*l.* contract, is, the builder who estimates according to specification finds that, though he has gone into the contract fairly and closely with only a small margin of profit, he is undercut by some hundreds of pounds by Jones & Robinson, who go in for the second method, and consider themselves sharp business people.

Some of your readers may say that the manufacturer asks bigger prices when specified, but in these times of competition this is not the rule. We all know a good article costs more than one of less quality. When certain articles are specified the manufacturer feels his goods are valued, that he has a reputation and for which he asks a fair price (his market price), which he expects to get, his future business not allowing him to cut the price at the expense of the quality.

When specifications are asked to be changed it is generally to benefit the contractor's pocket, which of course is all right unless it is detrimental to the quality of the work.

Take a given article from the bill of quantities:—"It shall be Blank & Blank's best A1 quality, equal to a certain specification." B. & B. know their A1 quality to be far superior to the standard specified, but, expecting a fair price, they supply the best quality as specified, feeling that the result of the work will bring them future business. Another manufacturer in the same line of business will undertake to supply an article to the standard specification at 5*s.* per ton or per thousand less cost, and which Jones & Robinson, the builders, estimate on; yet Blank & Blank know full well that they could supply a similar article at a much cheaper rate, and quite equal to the standard of specification, but their A1 quality being specified, they naturally prefer supplying it, knowing it will strengthen their reputation and lead to increased business.

If all contractors knew that architects would only allow specified articles to be used, far better work would be done. The fairest tenders would have a chance of being accepted, and the pockets of the architect's clients would not suffer for it.—Yours, &c.,

ONE WHO IS IN THE "KNOW."

March 4, 1895.

LEEDS ARCHITECTURAL SOCIETY.

AT the meeting of this Society, Mr. J. T. Micklethwaite, F.S.A., delivered a lecture at the Mechanics' Institute, Leeds, on "The Story of the Building of Westminster Abbey Church." Mr. E. T. Doddgshun (the president), in introducing Mr. Micklethwaite, said he was very well known in Leeds because of his connection with Kirkstall Abbey. Mr. Micklethwaite remarked that when we had the story of the development of one of our great churches it threw a good deal of light on other churches. These churches, as we saw them, were not

deliberately designed structures, but grew naturally, like a tree out of the ground. Some of our older abbeys, like Ripon and York, go right back to the seventh century, and gradually grew and became the great churches that we saw now, and he wished to show them how that happened at Westminster Abbey. Westminster Abbey was a national monument. It only became that by accident. It happened to be next to the residence of the king, and became the place of the coronation of the kings, and from the time of Henry III. onwards it was recognised as their place of burial. In the seventeenth century it began to be thought that burial in Westminster Abbey was the greatest honour that could be conferred upon a man after his death. That feeling grew up during the Commonwealth, and all the great men of the Commonwealth were buried there. The first Abbey was erected in the seventh century, but Bede, the great historian of the English Church at the time, did not mention it, though he mentioned York and Ripon, and we might take his silence as proof that in his time Westminster Abbey did not exist. In the eleventh century we get the fact that Edward the Confessor wished to build an abbey close to his house at Westminster, and there was an old abbey there. We were not told how old it was, but he set to work to rebuild it. The lecturer then traced the progress of the Abbey buildings, illustrating his remarks by references to plans, and showing how they continued to grow until the sixteenth century, every step being a definite step in the history of the Abbey.

GENERAL.

The Local Government Board have officially appointed Mr. James Green (Weatherall & Green, Chancery Lane) as valuer under the Manchester Corporation Act, 1894.

Lord Houghton, of Crewe Hall, Cheshire, has presented a site for a church on his estate at Blacon, near Chester. The work of erecting the new church will shortly be commenced, as half the sum required for building and furnishing has been raised.

At a Special Meeting of the Council of the Glasgow Institute of Architects, held in the chambers of Messrs. MacLean, Fife & Maclean, the president, Mr. T. L. Watson, in the chair, the secretary, Mr. C. J. MacLean, read letters which he had received from the Very Rev. Principal Caird, Sir John Stirling Maxwell, Bart., Sir George Reid, P.R.S.A., Sir Frederic Leighton, P.R.A., and Mr. R. Norman Shaw, R.A., intimating their acceptance and appreciation of the honorary membership which had been conferred on them by the Institute.

Mr. Percy Worthington, it is announced, will read a paper at the meeting of the Liverpool Architectural Society on Monday, the 11th inst., on "Churches of the Twelfth and Thirteenth Centuries in Burgundy."

Mr. Fowler, of Manchester, has been selected as engineer for a drainage scheme for the township of Helmsley.

Mr. C. W. Howden read a paper on "Organs and Organ Chambers" at the meeting of the Northern Architectural Association. His remarks were practically illustrated upon a small skeleton instrument provided for the purpose.

An Exhibition of the works of the members of the society known as Les Peintres Orientalistes Français is now open in Paris. There are works by MM. Gérôme, Benjamin Constant, Besnard, Renoir, Friant and others.

Mr. C. R. Carroll has been elected an associate of the Royal Society of Painter Etchers.

Mr. E. O. Sachs's paper on "Urban Fire Protection" has just been published by Mr. Batsford, of High Holborn, being the first of a series of "Studies in Municipal Economy."

Mr. A. Gilles, who was at one time the engineer for the docks at Southampton, died on Sunday in his seventy-ninth year.

A Lecture on "Art Tuition" will be given by Professor Herkomer at the Society of Arts on next Thursday afternoon.

Lord Mayo delivered a lecture in Dublin on Tuesday on the forthcoming Arts and Crafts Exhibition, which is to be opened on November 11. He said that what they lacked in Ireland were good designers.

A Tablet in commemoration of the opening of the Tower Bridge will be placed at each end of the structure. The tablet is of solid bronze, is 6 feet by 3½ feet in size, and weighs nearly 4 cwt. Ornamented at the top with the arms of the corporation of the City of London in bold and fine relief, it records the opening of the bridge by the Prince of Wales last summer, with the names of those who accompanied him, of the Lord Mayor and the sheriffs then in office, and of the aldermen and commoners composing the Bridge House Estates committee, whose device appears at the bottom. The name of the engineer, Mr. Wolfe Barry, is in the centre. The tablets have been cast by Messrs. Hart, Son, Peard & Co., of Drury Lane.

The Architect.

THE WEEK.

THE architects who carried out the self-imposed duty of meddling with the Bill which has become the Building Act of 1894 do not appear to have conferred many benefits on their profession or on the public. According to Sir JOHN BRIDGE, who is one of the most cautious of men in his speeches, "almost all the sections seemed to be so drawn as to be unintelligible; many were capable of two different constructions." The characteristics of amateur lawyers' work could not be more clearly described. The few cases brought before magistrates suggest that the Act is a colossal muddle owing to the twenty-two days' tinkering which the Bill underwent in the committee-room of the House of Commons. The case which came before Sir JOHN BRIDGE on Monday, and drew from him so decisive an opinion, related to Messrs. SHOOLBRED'S premises. Mr. WALLEN, the district surveyor, was summoned for declaring that plans of the altered premises were not in correspondence with the Act. It was supposed they were to be warehouses, but they were intended to be for domestic purposes, as residents for assistants, and counsel announced that they would have a magnificent character. Mr. WALLEN said he would admit they were domestic buildings, but as such they came under Section 41. That is the section which prescribes the diagonal line with its unlovely consequences. Sir JOHN BRIDGE inquired whether Mr. WALLEN understood the section, who remained prudently mute. The magistrate restricted himself to a matter of fact, and he decided that the buildings were to be used as offices, and therefore considered Section 41 did not apply. Mr. WALLEN'S objections were set aside or withdrawn. A district surveyor is bound to have the provisions of the Act enforced, but it cannot be expected that he will be able to convince people of his infallibility when he has to tacitly admit that he does not understand the clauses. The public cannot realise that the Act differs from most others in its unintelligibility. The district surveyor's position is, therefore, not enviable.

THERE is no mention of the Tope near the mouths of the Krishna, in the Presidency of Madras, in Mr. FERGUSON'S volume on Indian architecture, although it is larger than many examples which are described. According to a paper read by Mr. R. SEWELL before the Asiatic Society on Tuesday, the monument was of the most elaborate construction. First, foundations were dug deep in the soil, and a great circular base built of solid brick 148 feet in diameter. Above ground was a solid superstructure 5 feet high of large bricks, and in the exact centre of this was left a small cylindrical hollow, and the relic caskets were placed one above the other firmly built into the brickwork, the hollow being only about 9 inches in diameter. The outer caskets measured 2 feet 11 inches by 2 feet 6 inches and 2 feet 10 inches by 2 feet 3 inches respectively, so that it was abundantly clear that they could not at any time have been lifted out of the hollow. Above all this was constructed a dome, also of solid brick, having a base of 132 feet diameter, round which was a procession path of 8 feet broad. The whole of the outside surface was encased in marble slabs, so as to present a pure white glittering surface visible from a great distance. In the course of time much of the marble casing and the brickwork was removed by the inhabitants, and a few years ago a zealous officer of the Public Works Department utilised a quantity of the bricks for road-making, and most of the marble for the floor and walls of a small sluice in the canal close by. The caskets with the relics were respected in spite of all the changes which are brought about in two thousand years. The gold flowers, coins and precious stones are still intact.

"THE Monumental Effigies of Scotland from Thirteenth to Fifteenth Century" formed the subject of a paper read by Mr. BRYDALL, of the Glasgow Art School, before the Society of Antiquaries of Scotland, on Monday. The custom of carving monumental effigies in full relief, he said, did not appear to have prevailed in Scotland until the

thirteenth century the incised slab and a peculiar treatment of the figure in flat relief having been the previous monumental forms. While it was on record that certain tombs or effigies, such as those of The BRUCE and ROBERT II., were sculptured on the Continent and in England, the greater number were executed in Scotland. The destruction and dilapidation of these splendid works of art in Scotland was scarcely conceivable until the list was reckoned up. If they excepted the mutilated coffin lid of WILLIAM the Lion at Arbroath, the effigy known as MARJORY BRUCE at Paisley and the unidentified STEWART of Bute at Rothesay, they had no royal effigies left in Scotland. Of those of church dignitaries most had disappeared, while of those that remained none had escaped mutilation or decay. In strong contrast to the English effigies, with their beautifully enamelled heraldry and metal figures, the Scottish effigies, with the exception of two or three in marble, were of ordinary stone, and the only suggestion of the use of other material was in the hollows for the face and hands in the fine incised slab at Creich, also in contrast with England. There was no doubt that many of the Scottish effigied tombs were coloured and gilt. Mr. BRYDALL described the effigies at Arbroath, Swinton, Dundrennan, Douglas, Arbuthnot, Dunblane, Bourtie, Inchmahome, Paisley, Old Kilpatrick, Elgin, Fortrose, Aberdalgie, Rothesay, Renfrew, Cupar, Dunkeld, Beaully, Corstorphine, Falkirk, Dalkeith, Houston, Maryculter, Aberdeen, Borthwick, Seton and Rodell.

A PAPER on "Some Early Christian Antiquities" (unpublished) was read by Professor W. C. F. ANDERSON, M.A., before the Sheffield Society of Architects on Tuesday. The churches described were those discovered in 1893 and 1894 by an expedition in which the Professor took part. The first was a rock-cut chapel in a mountain side, about two miles from the valley of the river Mocestus, and three hours' ride north of the modern town of Bigaditch, in Mysia (Asia Minor). It is a projecting crag which hangs a couple of hundred feet above the valley below. The road is tufa, and in this is carved a church with porch, chancel and apse, and a side chapel. The church is very small, not more than 40 feet long from the door of the porch to the apse, yet all the features of a large church are imitated in this restricted space; the seats for the clergy with the bishop's throne in the centre run round the apse, the chancel is separated from the tiny nave by a triumphal arch, and the side chapel has a diminutive altar and credence table. Three crosses still remain over the inner doors, and a much mutilated wall-painting in the chapel shows that the church was originally decorated with emblems. There are many niches for lamps and votive offerings, and above the windows of the side chapel there is a carved relief, representing a dove standing in an arbour. The church is evidently an early one, but there seems to be no certain indication of its date. Similar chapels exist in Cappadocia and other parts of Asia Minor. Above the church is a small cell, also carved in the solid rock, which was probably the dwelling-place of a hermit priest who had charge of the shrine. The other churches are two discovered at the old Roman town of Doclea, in Montenegro. The larger is a basilica with an apse, a vestibule and a large court. It was paved with mosaic, and was decorated with many carved capitals, screens and windows. A large number of rudely-carved stone crosses point to there having been a number of altars besides the chief altar. The foundation of the seats of the clergy and the bishop's throne still remain, as does the platform on which the high altar stood. The date of the church is probably a little earlier than 500 A.D. The second church is much smaller, and is in the form of an elongated octagon. An inscription records that it was built by a lady called AUSONIA.

ON the 7th inst. Mr. CHARLES ALDRIDGE, architect, died at Claughton, near Liverpool. He held a good position among the architects of Lancashire, and at one time took an active part in the affairs of the Liverpool Architectural Society. Several churches were designed by him. Mr. ALDRIDGE was at one time a member of the Town Council of Birkenhead. He was fifty-three years of age.

JOHN BERNARD FISCHER.

ACCORDING to Mr. FERGUSSON, JOHN BERNARD FISCHER was "the most celebrated architect of his day." Yet, as often has happened with celebrated men, there is uncertainty about his name. In the baptismal register he is described as the son of "JOHANN BAPTISTA VISCHER, Burger und Bildthauer." MILIZIA and several other writers call him FISCHERS, and he appears to have sometimes adopted that mode of spelling. He claimed also to belong through his mother to the old and ennobled family of ERLACH, and his correct name would, therefore, be JOHANN BERNHARD FISCHER VON ERLACH. Genealogists and heralds have treated of his lineage and arms. If we refer to the subject it is only because, according to one theory, the architect, who was born in Grätz, in Bohemia, was of a family who came from the Netherlands. It is, therefore, not impossible that he belonged to the same family of craftsmen as PETER VISCHER of Nuremberg. The architect was a reformer of his art, for he caused the BORROMINI extravagance to be diminished, if not superseded, in Vienna and other places; nevertheless, he was as independent as any of the Dutchmen in dealing with Classic details.

As the register announces, his father, JOHN BAPTIST FISCHER, was a sculptor or carver of architectural ornament, and, as far as can be traced, the family seem to have been craftsmen. Mr. FERGUSSON gives 1650 as the year when the child who was destined to become so prominent in architecture was born, but that date is six years too early. The date given for FISCHER's death is also incorrect; it should have been 1723 instead of 1724. The uncertainty about time corresponds with the obscurity in other matters relating to FISCHER. Between 1656, the year of his birth, and 1680 is a term on which no biographer of the architect can illuminate. It is supposed that he studied in Prague, and was engaged on the Gallas'schen Palace; but the grounds for the belief are insufficient. His connection with that building was of a later date. In such cases it is wisest to assume that the ordinary course of instruction would be followed. The architect's father was an able man, and he was likely to utilise young FISCHER's talents as early as possible. In the seventeenth century both architecture and decoration were in a flourishing state in Austria. The terrible Thirty Years' War had come to an end in 1648, six years before FISCHER's birth, and efforts were made to restore the country to its former condition. Numerous artists from Italy were engaged on palaces for the nobles and churches. A sharp youth who was able to carve would find the best sort of instruction, which is practice in competition with men of experience, without going far from Grätz. FISCHER's father would be likely to give ample opportunities for study to his son. The elder was employed by some of the nobles of the district, and especially by the DIETRICHSTEIN family. The latter extended their favour to his son and grandson. It would, therefore, be not unusual if some of those nobles were attracted by the young artist, and became his patrons. It was probably aid of that kind which enabled FISCHER to travel to Italy, and to reside in that country during several years.

Italy was a school of the highest art before FISCHER's arrival and subsequently, but a number of causes combined in the seventeenth century to make it supersede all others for an Austrian. The empire was almost dominant over all Italy, and as some compensation for foreign rule Italian artists were allowed to have their own way in Austria. But there was another and more important relation between the two countries. In the struggle of the Reformation Austria was separated from Germany, and it was of vital importance to the Roman Court that Austria should be kept from following the new ways. The clergy contrived to gain the upper hand, and ruled civilians and soldiers. When ISOLANI, in "Wallenstein," is made to recount how, when he went to Vienna to arrange for remounting one of his regiments, he was sent to a Capuchin who had charge of that department, the poet was not drawing on his imagination. In all matters of taste the clergy were no less omnipotent. Among the means employed to gain power over laymen fascinating churches were prominent. The gloom and severity which at various periods characterised churches were ignored. Pictures of martyrdoms were not condemned,

but when they were introduced they were placed in a setting which imparted a different character to them. The indiscriminate employment of sculptors and painters as architects was operating to produce a result that was similar to what the ecclesiastics desiderated. Painting made sculpture more flexible than the Greeks or the early artists of the Renaissance could approve, and painters and sculptors tried to impart the same quality to buildings. Unfortunately the style became associated not only with orthodoxy, but with the new spirit of the Church. Walls could not easily be made suggestive of action, but in many places instead of planes we see projections that are convex and concave, and the divagations of mouldings are unprecedented. The old repose of architecture was treated with contempt, and restlessness was preferred. In Italy the people, with all their artistic aptitudes and familiarity with ancient examples, could not resist the new style. What chance was there for stemming its advance in Austria? In the churches of the seventeenth and eighteenth centuries in the cities of that country, we see a development rather than an imitation of the eccentricities which characterised the Roman churches of the revival.

At the time of FISCHER's visit to Italy the majority of the native architects would be engaged in working out the restless style that was the vogue. It is creditable to him that he was not carried away by the excitement. As a sculptor he would have been able to realise how much of the effect depended on a tricky dexterity, and when he had resolved, like so many other artists, to attempt architecture, his attention was given to work of a better time. In FISCHER's buildings it is easy to perceive an effort to combine two modes of treatment. There are in his churches especially parts which show the pure Italian spirit, but with them are other parts exhibiting a submission to the necessity of the time, which demanded novelty regardless of the sacrifice it entailed.

It is supposed that FISCHER had passed his thirtieth year when he returned to Austria. He was as versatile as any artist of the Renaissance. He could exercise the arts of the sculptor, painter, medallist, etcher and architect. But the Italian artists were not all turned adrift on his arrival. FISCHER's period of waiting for commissions was, however, shortened for him by one piece of luck. He received the appointment of teacher of art to the Crown Prince. That at once secured for him the notice of the Court and grandees, and future success was insured. Yet, strange to say, the first work which brought him reputation was a mere temporary structure, a triumphal arch erected in 1690, when FISCHER's pupil returned to Vienna as king of Rome. Architecturally it resembled the Roman arches, and it was enhanced by paintings, tapestries, &c. This scenic work—MILIZIA describes it as "un capo d'opera di stravaganza"—seemed to cause almost as much rejoicing as the coming of the prince. The Viennese felt they were not barbarians, for a countryman was able to erect a structure which surpassed what was done by the foreigners. A medal was struck to celebrate the occasion, and for a time FISCHER's arch was accepted as one of the wonders of the world. Commissions from the higher clergy and the nobles were forthwith offered for his acceptance.

The Archbishop of SALZBURG, in whose diocese Italians such as ZUGALLI and SOLARI had long possessed a monopoly, was one of FISCHER's first patrons. A church for the Ursulines displayed his capacity. Several other churches, a great presbytery, collegiate buildings and many others of an ecclesiastical character followed. Salzburg possessed a building, mostly of white marble, which was intended to shelter the archbishop's horses. FISCHER was employed to make some alterations in it, and his success led to the commission for the imperial stables in Vienna, which some critics consider to be the most effective of the architect's works. As stables the block has no rival. FISCHER was also employed in some works at the cathedral, but he was so reverential towards the design of SCAMOZZI and SOLARI that local archæologists are not agreed about what was undertaken by him. One of his most important works in Salzburg was the Church of the Trinity, which was commenced in 1694, in which there is an oval cupola which seems to be a first thought for one of the characteristic features of the church of St. Charles in Vienna. The University Church is another costly work that is well

adapted for solemn functions. It also shows in some parts his admiration for elliptical plans. In these buildings FISCHER was careful to give the preference to his countrymen who were painters and sculptors. In that way he accomplished an industrial revolution in Austria and one without parallel. The economic effects of FISCHER's control would form a subject for a treatise that would be more fruitful in suggestive conclusions than many which now obtain attention. The Austrian architect determined the question of foreign competition in an advantageous manner without other aid than his own courage and organising power.

The Salzburg buildings were ecclesiastical. Whether the Castle of Klessheim, which was a country house of the archbishop's, should be included among that or a secular class need not be discussed. FISCHER in many ways resembled modern architects rather than his contemporaries, and one of them was his production of illustrations of his proposed buildings. An etching of his design for the Schloss exists, and it suggests a late Italian villa, with an abundance of sculpture in prominent positions, and other details suggestive of sumptuousness. FISCHER was not destined to complete the building; in fact, it never was fully completed, nor was his design respected. The character which the building possesses was imparted to it by BERNARD STEWART, a remarkable man who merits notice in every book that treats of "the Scot abroad." He was born in the beginning of the eighteenth century, and did not reach his fiftieth year. Throughout his life foreign air oppressed him. He became a priest, and taught mathematics in the Salzburg University. He also practised as an architect in Austria. Schloss Klessheim was entrusted to him among other buildings. This remarkable man died in Italy in 1755.

FISCHER was more fortunate with the castle of Schönbrunn, which serves as an Austrian Windsor. It was not, however, erected on the feudal or English plan. Versailles was then dazzling all Europe, and big and little kings had set their hearts on something resembling it. As Mr. THACKERAY said, it is incalculable how much LOUIS XIV. cost Germany in imitations of the royal bigness and belongings. There were no millions in the Vienna treasury to be wasted over buildings, and accordingly Schönbrunn is only a stucco Versailles, although Austrian courtiers have been known to declare it surpasses the French pattern in style and surroundings, more especially as the selection of the site and the character of the buildings were supposed to be due to the genius of FISCHER's pupil, the Emperor JOSEPH I.

The nobles followed the example of the emperor in expending money on palaces. FISCHER's name must be remembered in Vienna as long as the Schwarzenberg Palace, the Liechtenstein'schen Palace, the Trautson Palace, Prince EUGÈNE's Palace, the Batthyany'sche Palace and others endure. Some of them would pass for Queen Anne or Georgian buildings if the fantastic window-heads could be removed. An architect who was so prominent deserved a title in a land where an addition of the sort brings respect. From 1705 FISCHER VON ERLACH was his name, and after his father's death his son, who was also an architect, was raised to a higher grade.

FISCHER's churches in Vienna are remarkable. His admirers hesitate about his part in the Peterskirche, a sort of imitation of the Roman building, because it does not correspond in style with any of the other works of the architect. But there is no doubt about his church of St. Charles Borromeo. It was the subject of a competition in 1715. The Emperor's taste was held as supreme in such a case, and he unhesitatingly decided in favour of FISCHER. We believe it is doubtful whether the two immense detached columns with the spiral bas-reliefs which stand in front of the building were represented in FISCHER's design. The church is on a novel plan; the central part of the façade is a Corinthian temple on a small scale, which is extended on both sides beyond the walls of the main building, with a pavilion flanking each end. Or we may describe the front as a long corridor leading from one open pavilion to another. The nave of the church is an ellipse on plan, with side chapels and a long chancel. Over the nave is a cupola which corresponds on plan with it. The innovation is not without its advantages. In circular or octagon churches, as in

Berlin and Brussels, the high altar loses its importance, for there is no reason why it should be in one position rather than another. But an elliptic plan almost appears to have a sort of apex, and when, as in Vienna, the chancel is deeply recessed, the attention is at once directed towards the most important part of the building. The exterior appears to suggest a great many parts, which appear to have independent uses, and in fact it would be easy to make several buildings out of the church, although the interior expresses unity.

FISCHER, as we have said, was fond of representing his works, but he sometimes neglected to produce views, and in consequence it is not always easy to identify his buildings. He did not restrict his skill to his own buildings. He brought out an immense architectural atlas, in which he tried to suggest the whole history of architecture. In many cases his views are only imaginative efforts, although valuable in suggesting that without proper evidence the clairvoyance of an able and practical architect is misleading. FISCHER was also as contemptuous towards Gothic as any fine gentleman of the eighteenth century. But his attempt was the first of its kind, and if with all the resources of modern times there is still no adequate representation of the variations of architecture, we should be merciful towards the effort of the Bohemian architect.

GREEK THEORIES OF ART AND EDUCATION.

A LECTURE was delivered in Dublin on the 6th inst. by the Rev. J. P. Mahaffy, D.D., F.T.C.D., on "Greek Theories of Education." He said he felt it his first duty to explain that the subject was by no means one of mere antiquarian curiosity, for the theories of the Greeks were worth considering by practical men and women of the nineteenth century. Most curiously old Greek life was more developed, more civilised, more modern in some respects than the Europe of the Middle Ages. It was common to say that the Greek race possessed such genius that educating them was an easy matter, but that was not the view taken by the Greeks themselves. They heard very little from them about natural genius. If any of them did great things in politics, in philosophy, in war, they would find in nineteen cases out of twenty they ascribed it, not to his genius, but his training. The question arose how far did they get with this training, and what did they do with it. He would take its most obvious result, their literature, the level that was attained by their historians, their orators and their poets. If they honestly compared what the Greeks had left them with that produced by all modern Europe they would only find their equals in the very greatest poets and thinkers, and they would have to call in Dante, Goethe and Shakespeare to rival their poets, Gibbon to rival their historians, and in many branches of literature, such as eloquence and philosophical prose, they would not find their equals even amongst the moderns, who used them freely as models. This literary excellence was continued through several centuries and was attained by a great number of writers, but among them all they would not find one case of what was called an original genius who made up for the want of education by his natural inspiration. They were all anxious artists, trained by masters and adhering to fixed principles in their literary work. It was remarkable, too, that almost all of them postulated a highly-trained and even learned audience, which not only took an interest in the larger and nobler problems of life, but were able to follow recondite allusions and subtle arguments. The people who could appreciate Æschylus or Sophocles were far more thoughtful and acute than any modern audience he could name. How was it then, it would be said, that they seemed to have accomplished so little in science? Were they sure it was little? What about Euclid's "Elements," so perfect and logical a text-book that all their schoolmasters to-day were afraid to venture upon any other elementary geometry? He could show that in mechanics, in higher geometry, in physical geography, and in hydrostatics the great men of Alexandria led the way to their modern discoveries, and that if the theory had not been found and the proper conditions defined of many of their modern problems by the Greeks, modern science might now be far more backward than many perhaps imagined. And they always professed that what they had attained was got not by genius but by training. The external circumstances of their education were of some importance to modern educators when they desired to institute a comparison between the ancients and the moderns. Regarding the burning question of female education, he could tell them nothing, for although Plato insisted in his ideal state that girls should receive exactly the same training, both physical and mental, as boys, that was only carried out to some

extent among the Spartans where the training was merely physical, together with some discipline in obedience and respect for the old. They were told that the results were physically excellent, but the Spartans set such small value even upon reading and writing that if they produced strong and beautiful women it was all that they aimed at, and, indeed, they knew that in times of war or other social disturbances these ladies were more turbulent and difficult to deal with than the enemy. They could put that out of account in the present discussion. They might be sure that there was high education for women at Lesbos at the time the island produced the poetess Sappho, whose fragments showed the very highest art, yet they only knew there were associations of young women for that purpose, whose freedom of speech and action caused no little scandal amongst the Greek societies who were in favour of the seclusion of women. In the famous tract of Xenophon upon the training of a young woman to be the efficient mistress of a house, he assumed that she came to her husband quite ignorant of all arts save those of dyeing her hair, painting her face, and otherwise improving her appearance. The habit of living in towns and not scattered through the country, as many of the richer classes were nowadays, made it possible for the great body of the nation to do without that great modern expedient, the boarding school, where boys were sent away from their parents and put into the hands of professional strangers, who trained them somewhat as the whippers-in trained a pack of hounds to their work. Not that the Greeks did not know the system as well. It was practically the plan adopted at Sparta, where boys lived till they were grown men in a sort of common barracks, quite separate from their parents in the same city, under discipline as regarded diet, deportment and military bearing. Though Plato highly approved of this plan, and thought that in the ideal state not only boys but even girls should be taken away from the charge of their parents, it was not thus that the great intellectual pre-eminence of the Greeks was attained. They did not find that any other State or any other practical educator, except perhaps Pythagoras, ever resorted to that unnatural and extreme expedient which induced so many people nowadays to pay large sums to escape the burden and the care of training their boys. The whole Greek system might be fairly described as a day-school system. Boys lived at home, and only went for some hours—not very many—to a schoolmaster. They knew that the number of subjects was very small compared to the school programmes of the present generation, and they might fairly compare it with that which educated their gentlemen and their men of letters fifty years ago, and all through the earlier time since the revival of learning. The selection of a few subjects was partly for necessity and partly for choice. There was not then the temptation to learn the history of all the world or its geography, or the applications of geometry and arithmetic; above all, they had not the mania now extant for pretending to learn several modern languages. In Greece, in her golden days, boys were only trained in the masterpieces of Greek literature, in a knowledge of the Greek poets, and perhaps of orators and historians; but when Greek culture spread to neighbouring countries, and Italians and other foreigners aspired to Greek culture, it was quite fixed that this could only be done through the Greek language; and so all that sought that training had to do in that way and that way only. Their great theory was that a boy should learn a few things, two or three great subjects, and learn them well, and not one that he should select, as lads may do in Oxford and Cambridge, and abandon all the sister studies which ought to distinguish a University man from the tradesman in a particular line. To allow parents or boys themselves a choice of subjects would never have been tolerated among the Greeks unless it was the desire of the parents to bind their son to a trade, in which case the master taught him but one thing, and he became a mechanic or an artist, and did not aspire to the higher walks of life. It was another part of their theory that they should not learn out of books, or by reading up books at home, or by being examined in books, but by the living voice and intercourse with the teacher. It might be said that if the Greeks had discovered printing they would have used books in education as they were used at present. The lecturer did not think so; they had just as many books as they wanted. Papyrus was cheap, and there were plenty of book-sellers and trained slaves to copy out books in a neat and precise hand as different from ordinary writing as type was. They could not think what a benefit slave labour was to a nation which had not our appliances for multiplying work by machinery. An Athenian could have procured as many primers as he wished for at a cost not much greater than he could at the present day. Education was with the Greeks essentially a State affair. As regards music, it was the habit to teach boys a certain amount of singing and playing, for they regarded music as having a close relation to morals, and were wont to guard carefully against the practice of what they called immoral music—immoral not because of the words, but because certain scales and harmonies were of a loose and relaxing character and un-

strung the mind, while others were manly and inspiring, promoting bravery and temperance. That was one of the fundamental contrasts between our notion of school training and theirs. It did not occur to them in the present day to examine whether Chopin or Beethoven may not have a secret moral or immoral effect upon those who study them; they took it for granted that music, like drawing, was a mere artistic pastime, not harmful in itself, though it might be associated with harmful objects. Both the Greeks and they in these countries agreed that physical exercise was an essential part of education, and it was to this agreement that they might attribute the superiority which the Greeks in the past and they in the present day showed over the other nations of Europe. Turning to what corresponded amongst the Greeks to university education amongst us, there was a certain class, with means and leisure, who, after their boys had got their ordinary schooling and had done their compulsory military service, desired to train them for public life and for the professions. They must remember that university education in their minds, and in the minds of any people who thought about it now, was not a theory for the masses. The notion underlying the new schemes here and in England, and which underlay what many thought a great sham, called the University Extension movement, was that every sweep and tinker had a right to University education. It was of course perfectly absurd. What such classes wanted—he meant in the sense of what they ought to get—was a thorough technical education in the trades which were within their reach, and which should be maintained in order that the country might prosper. The son of a farmer with twenty acres or less had no claim to learn Greek and Latin, and thrust himself into the learned professions, where he would be an inefficient and discontented member of a society which justly despised him. What he wanted in the proper sense was to be taught to plough, an accomplishment which he (the lecturer) was told was quite rare in this country and commanded high wages, to read and write, to keep simple accounts and to learn what was good and efficient farming, superior methods of managing land and feeding cattle, instead of spending his father's earnings in setting up as a tenth-rate doctor or lawyer. He was not by this severance of classes into university and non-university classes advocating the suppression of genius. That was absolute nonsense. A boy who really had genius had had for the last century, and had now, ample means of rising out of his obscurity. They would find it hard by any system to choke genius. The real danger was to puff up the average boy. Above all the Greeks had never condescended for one moment to the theory that by mere examinations they could pronounce a man educated, or that by competitions in books they could select the fittest candidate for the public service. They insisted that their pupils should never be in a hurry to know this or that, or be qualified to hold this or that appointment, but that they should regard higher education as a matter of leisure. The very word school meant leisure in Greek. It seemed to be the ideal of the modern Radical that by a succession of schools—primary, secondary, intermediate, collegiate or whatever the jargon was—the pauper could be made a labourer, the labourer a farmer, the farmer a mechanic or shopkeeper, the shopkeeper a professional man, the professional man, he supposed, a political thinker, the political thinker a legislator and so on, to whatever the highest goal of mankind was, and that when such a system of raising the poor and ignorant was perfect they might, with the aid of the accumulated wealth of the idle classes, which was to be solemnly and with great show of justice looted, attain to a more and more perfect happiness in this world, ending, he supposed, in a millennium, not under a theocracy, but under a one man one vote democracy.

In his second lecture Professor Mahaffy treated of "Greek Theories of Art." He said he must first enter into some general considerations upon art which were necessary to the understanding of the principles followed by the Greeks. Had they ever, he asked, thought out for themselves what the domain of art was or what it desired to accomplish? The subject was not without obscurity and difficulty, but they had three great ideas of perfection first analysed by the Greeks and since adopted by all thinking people as the only possible forms of the ideal. They were the good, the beautiful and the true. Whether those three were or were not ultimately reducible to one, whether they did not merge into the knowledge of the source of all perfection, was a metaphysical question beyond their present scope. For us the three were distinct, while the science of morals aimed at the good and the true as aiding the good, and the science of æsthetics (to use a very misused term) aimed at the beautiful and the true so far as it aided the beautiful. The two sciences were certainly in our practical life quite distinct, for while those who devoted themselves to the pursuit of the beautiful were very careless about the good, we knew from the experience of our pious people, especially of the Nonconformist Protestants, that those who were keenest about the pursuit of the good cared very little for beauty. They had to rise to the heights that Plato did to grasp

that no true beauty could exist save in what was good, and *vice versa*. What he was, however, now concerned with was rather the relation of the true to the beautiful, for while the latter ought to be in every case the aim of art, yet so important in the matter was truth that most of the world's art had failed and decayed from neglecting that great condition. Men had tried to construct the beautiful at the expense of the true, and so art had become unreal, and as soon as art lost touch with the true, which was only another word for reality, it lost its hold upon men and fell into neglect and decay. But, on the other hand, if the study of the beautiful and its representation in art were to confine itself absolutely to reality, and never condescend to violate truth, then art would lose its great function, which was to create ideals for men, to show them beauty greater and purer than that of ordinary life. Whether in music or poetry, or in sculpture or in painting or in architecture, the same great law held good—if art did not bring us nearer to the ideal, to something higher than ordinary life, it was no true art. There was an apparent exception in the case of realistic painting, which he only mentioned to caution them against being misled by it. There were portraits of ugly people with wonderfully accurate and rich drapery and furniture. But accuracy, though admirable, was only to be commended as a very perfect handicraft, as a great difficulty overcome by skill and patience—nay, won by a natural gift. Art must seek beauty while not abandoning reality; yet as art must endeavour to translate the real into the ideal, so some truth must be sacrificed to beauty, while no doubt some imaginary beauty must be sacrificed to truth. The perfection of the art of a nation, of an epoch, or of a man consisted in the instinct with which those two contrasted elements were combined. That was artistic genius, and in it the Greeks excelled all the nations of the earth, for they understood how to combine the unreal and the real with a boldness and tact which surprised the modern critic. Professor Mahaffy illustrated this tendency amongst Greeks by referring to their representations of centaurs on the Parthenon, which he described as an unreal and impossible animal creation. Turning to a far more curious case, poetry, it might be said here, at all events, they began with the natural. Nothing of the kind. Homer, the first great master who opened a new vein, was not a child of nature, but was highly artificial, and according as each new species of poetry arose there was still artificiality. It was still more remarkable in their oratory, and when Demosthenes broke through some of the unrealities of earlier oratory, and allowed himself liberties to make his speech seem natural, it was only in the most sparing way and without sacrificing the taste for artificiality that underlay Greek art. The Greeks knew as well as he did that great poetry, like great music, should not be descriptive but suggestive. The Greeks had no inspired books (in the sense of the scriptures) in any established moral system in their religion, and therefore they were obliged to seek the moral emotions which were to be found in religion and in their art, by which he meant their poetry and their music. That made them accentuate their poetry in a way wholly foreign to the present higher criticism, to which a strong moral intention, the working round of a story into a sermon in praise of virtue or in censure of vice was most distasteful. A poet who posed as a moral teacher in that sense was now considered almost to have betrayed his mission, to have sacrificed the ideals of art to the commonplace of morals. Not so the Greeks. Very few of those present would take up Homer as a moral teacher, yet he was taught to centuries of Greek children, as the Bible was taught, with comments and explanations to show how all the private and the civic virtues were inculcated in his poems. It was possible with a good deal of contrivance to effect this with Homer. It was not so with the early lyric poets. But with regard to the tragic poets, who had openly professed that their main object was to make men better, it was true that their main object was well disguised and presented in the solution of great and tragic problems. It was not the commonplace instruction of proverbs or of children's rhymes, but nevertheless the moral intent was there far more consciously and definitely than it was in Shakespeare. The case was even more remarkable and curious when they came to read the consistent and repeated declarations of the theorists about Greek music. They were in a far worse position as regarded the possibility of appreciating what was thought in this case. For while there was more than enough great Greek poetry extant to enable them to form an opinion on this point, the remains of the Greek music was wholly strange to those of the present day. They possessed the notation, and could set down the notes of the recovered passages with certainty, but there resulted a succession of sounds which they could not reduce to any modern melody or harmony without taking the wildest liberties. Nevertheless, the Greeks who, in all the other arts which they transmitted to us were our acknowledged masters, never for one moment suggested that their music was inferior to their other arts. But any modern musician would be ashamed to produce the "Hymn to Apollo," and yet to this stuff the Greeks attributed the most momentous

moral influences. What was the meaning of all this? They must remember that on the question of art they must attend carefully to what their greatest masters had to say. The problem was not ripe for solution until they had recovered more Greek music, and could understand both their melody and their harmony if they had any. But the constant presence of this Greek theory had led him (Professor Mahaffy) to believe that the moral influence was vastly underrated which mere music, apart from words, had upon the minds of youth. It was the modern habit to set children to learn the subtle art, which, if they had any deep feeling for it, probed them to their inmost soul, and stirred within them a crowd of half-conscious emotions. Yet even now they suspected that in so doing they might be producing some queer moral disturbance in their nature. Who knew whether the constant repetition of the emotions excited by a nocturne of Chopin, or an adagio of Beethoven, might not in the end mould the character and set the mind upon subjects which had better be left alone? Who knew whether the temper might not be injured, the virtues of patience and endurance, the precious gift of constitutional contentment, might not be filched away from it if they were perpetually agitating their souls with the storm and strife of Wagner's rhapsodies? The Greeks would give an answer in the affirmative. They would urge that all these vague, undescribed emotions, which are and ought to be excited by music, have their effect upon the whole moral nature, and they would point to the lives of famous artists to show how deleterious this art had been to their morals. The poetry, sculpture and architecture of the Greeks were certainly on a higher level. Their painting may have been so, but their music was exceptionally inferior. Then this strong opinion about the moral value was even more difficult to explain away. But the probabilities were surely that men who had so subtle and sure an instinct for the charm of the voice in language, whose poetry was so essentially melodious, could hardly have been mere children groping in the dark in the treatment of sustained tones which would produce music. If so, here was a whole department of education upon which they had no theory at all, and which required searching investigation. Or if artistic talent was now indeed dissociated from moral nature, then the modern human being was far more different from the old Greek than any of them could imagine. He now turned to a great contrast between Greek art and modern day art. It was that, while among the Greeks all the fine arts were closely associated, with modern art they were almost wholly disassociated. In Grecian times poetry was not meant to be read or even recited so much as to be sung to music. The poet was essentially a singer, and the whole province of music was to accompany poetry or that rhythmical movement which was called dancing. Discounting some rare exceptions, it might be declared that none of the fine arts amongst the Greeks were isolated, but always appeared in close association with the sister arts. He might go further and say that they were associated by the cognate nature of the subject-matter with which each and all were concerned, and that subject was religion. This, then, was what he meant by this large harmony of all Greek art which produced a consistent effect upon modern art as it did upon the Greeks, and, so to speak, forced each of the Muses to keep pace with her sisters.

TESSERÆ.

Effects of the Artist's Personality.

THE dead, inanimate material that the artist handles—be it a lump of clay, a stretch of canvas, a heap of stones—is quickened into life, transfigured by the man's communication of his own spirit to the thing. The stretch of dead canvas becomes sensitive and alive under Leonardo's hands, and the thing painted is immortalised; for the flesh of Mona Lisa still glows, the pulses of her neck seem still to palpitate, the carnation upon her cheek is still there, the wistful eyes still gaze out beyond the picture, beyond you and into eternity. The face of the landscape that Wordsworth and Turner painted had nothing uncommon about it to the eye of the village yokel, but the man of genius as he paints it imparts to the picture by some subtle magic his own unique imaginative expression, and lo! it acquires a new influence—the added gleam—"the light that never was on sea or land, the consecration and the poet's dream." It would seem then that a work of art—poem, building or painting—gets its singular gift of attractiveness from the personality of the man. The artist strikes the imagination of others by pressing into his work his own imaginative qualities. Sir Joshua Reynolds puts the matter thus:—"It is not the eye, it is the mind which the painter of genius desires to address." The artist, he says, will not "waste a moment upon those smaller objects which only serve to catch the sense, to divide the attention, and to counteract his great design of speaking to the heart, and it is this power of address that entitles painting to rank as a sister of poetry."

The Horizontal Line in Composition.

It was a remark of Stothard that "great grandeur might be obtained either by a very high or a very low horizon; but when the horizon is placed in or near the middle of the picture, grandeur of composition must be sought from some other principle." In many of his own pictures we have fine examples of the advantage of a high horizon, and Titian's *Peter Martyr* affords a noble instance of the grandeur of a low one; indeed, Titian's compositions of *The Death of Abel*, *Abraham and Isaac* and *David and Goliath* owe much of their grandeur to the horizon being entirely below the boundary of the picture. This choice was suggested by the adaption of those great works to ceilings; but there is no reason against such a choice in pictures that are to be hung above the eye and a strong reason in favour of it, namely, that the effect will be truer. Hogarth's facility and taste in composition were very great, but some of his interiors would have been more true in general effect had he placed his point of distance farther from the plane of the picture, or been less fond than he was of oblique perspective. This is particularly observable in one of the most admirable of all his works, the breakfast scene of the *Marriage à la Mode*, in which neither the floor nor the ceiling appear to be level unless the eye is placed so close to the picture as to be unable to see any part of it perfectly. Hogarth seems to have considered it to be always proper that the spectator should suppose himself to be in the apartment represented. But there is no absolute necessity for this. The side of the room not represented may be imagined open, as in many of Wilkie's compositions and as in scenes on the stage; indeed, it is best as a general rule to suppose the eye of the spectator to be at a distance from the surface of the picture equal to a line drawn diagonally across it from corner to corner. The Dutch painters of interiors have generally adopted a nearer point of distance, but then they always preferred parallel to oblique perspective, and this choice greatly assists the level look of their floors and ceilings. They often, both in interiors and exteriors, availed themselves of the advantage a near point of sight gave them in introducing one or two long oblique lines, which, as they managed them, gave much grandeur and effectually excluded a tame or commonplace appearance from compositions in other respects extremely simple. As to lines and forms of beauty, the serpentine line is unquestionably, in itself and alone, more beautiful than the straight line, and a round or oval form more beautiful than a square one. But every line in turn becomes a line of beauty from situation and contrast, and in the same way every form may be made an object of beauty. Hogarth recommended the pyramidal form of composition as the best, but nature, by the laws of perspective makes every form of composition in its turn agreeable to the eye; and though in Hogarth's works we trace much of the pyramid, yet he did not adhere to it so constantly or so rigidly as to give too great an appearance of artifice. One thing may be said in favour of the pyramid, where the composition rises high above the horizon—that it conforms to the law of perspective by which all perpendicular lines terminate in a point. It is not a little curious that Hogarth in his eagerness to support a favourite theory, tells us that the sculptors of the Laocoon made little men of the sons rather than violate the principle of the pyramid in the composition of the whole. He had perhaps never seen a cast of the original group, and may have known it only from bad engravings or copies, otherwise it is inconceivable that he could have mistaken the boys for little men. His "Analysis of Beauty" is, however, a book that every painter should read, as it can never be consulted without profit, if the reader be on his guard against too implicit a reliance on the reasoning of the author where his theories of the serpentine line and the pyramid are concerned.

Dreamers and Workers.

There is, in the present day, an overplus of raving about genius and its prescriptive rights of vagabondage, its irresponsibility and its insubordination to all the laws of common sense. Common sense is so prosaic. Yet it appears from the history of art that the real men of genius did not rave about anything of the kind. They were resolute workers not idle dreamers. They knew that their genius was not a frenzy, not a supernatural thing at all, but simply the colossal proportions of faculties which, in a lesser degree, the meanest of mankind shared with them. They knew that whatever it was it would not enable them to accomplish with success the things they undertook, unless they devoted their whole energies to the task. Would Michel Angelo have built St. Peter's, sculptured the Moses, and made the walls of the Sistine sacred with the presence of his gigantic pencil, had he awaited inspiration while his works were in progress? Would Rubens have dazzled all the galleries of Europe had he allowed his brush to hesitate? Would Beethoven and Mozart have poured out their souls into such abundant melodies? Would Goethe have written the sixty volumes of his works—had they not often, very often, sat down like drudges to an unwilling task, and found themselves

speedily engrossed with that to which they were so averse? "Use the pen," says a thoughtful and subtle author; "there is no magic in it, but it keeps the mind from staggering about." This is an aphorism which should be printed in letters of gold over the studio door of every artist. Use the pen or the brush; do not pause, do not trifle, have no misgivings; but keep your mind from staggering about by fixing it resolutely on the matter before you, and then all that you can do you will do; inspiration will not enable you to do more. Write or paint; act, do not hesitate. If what you have written or painted should turn out imperfect you can correct it, and the correction will be more efficient than that correction which takes place in the shifting thoughts of hesitation. You will learn from your failures infinitely more than from the vague wandering reflections of a mind loosened from its moorings. Because the failure is absolute it is precise—it stands bodily before you—your eyes and judgment cannot be juggled with—you know whether a certain verse is harmonious, whether the rhyme is there or not there; but in the other case you not only can juggle with yourself, but do so—the very indeterminateness of your thoughts makes you do so. As long as the idea is not positively clothed in its artistic form it is impossible accurately to say what it will be. The magic of the pen lies in the concentration of your thoughts upon one object. Let your pen fall, begin to trifle with blotting-paper, look at the ceiling, bite your nails and otherwise dally with your purpose, and you waste your time, scatter your thoughts and repress the nervous energy necessary for your task. Some men dally and dally, hesitate and trifle until the last possible moment, and when the printer's boy is knocking at the door they begin. Necessity goading them, they write with singular rapidity and with singular success; they are astonished at themselves. What is the secret? Simply this, they have had no time to hesitate. Concentrating their powers upon the one object before them they have done what they could do.

Grouping in Painting.

Nature everywhere arranges her productions into clusters, and to this end she employs a variety of means. The heavenly bodies are grouped by attraction, flowers and trees by the natural means by which they are propagated, while the social instincts congregate man and most other animals into societies, and the same instincts impel in man as well as in many of the inferior creatures the grouping of their habitations. Grouping is therefore an almost universal law of nature, and a scattered display of objects, though it may sometimes arise from accident, is in interruption of this law; and we consequently find that grouping in art is agreeable to the eye, and though single objects are also agreeable, we are never satisfied with a scattered look in composition. In observing crowds in the street or groups in a drawing-room we notice many repetitions of similar attitudes, and in herds of cattle, flocks of sheep, &c., we remark this also. Repetitions of forms and shapes are likewise of frequent occurrence in trees, flowers, the outlines of mountains, clouds, &c. Now the picturesque styles of composition, as they are called, avoid the imitation of these appearances as too formal for art; but this, like every other rejection of a natural principle, only produces mannerism—which sort of mannerism was carried to its greatest extreme by the French painters of the time of Louis XV., painters who are now all but forgotten. It is true there is another extreme in some styles in which the repetition of attitude becomes pedantic or theatrical, as in the "Oath of the Horatii" by David; but in the best compositions of Masaccio, of Raphael and of Poussin, these repetitions occur exactly as they do in nature, and in the works of the best landscape painters, and particularly of the Dutch and Flemish schools, we see the repetitions of forms in inanimate objects given with the same unaffected truth. It is such modes of treatment in which the true artlessness of art consists; artlessness which is indeed the perfection of art, and the farthest possible removed from that artlessness which arises from ignorance, the artlessness of very early art and of the designs of clever children. Peter de Hoo, the most consummate painter in his particular style that ever lived, whose pictures, to those who are content with the humble subjects he for the most part gives us, leave nothing to be desired, is a far more artless painter, in the sense in which artlessness is to be admired, than Cimabue. There is so little of the appearance of study in his compositions that they look as if anybody could have put the objects they contain together as he has done it. But let the attempt be made, and the difficulty will at once be felt; or let it be attempted to improve any one of his lines, and the impossibility will soon be discovered. Art never has been and, we may well believe, never will be carried to greater perfection in its technical qualities than in some of his works. All improvements in composition, from the infancy of art to its full maturity, are strictly and solely the result of the discovery of the principles by which nature makes assemblages of objects agreeable to the eye, sometimes by giving variety to regular forms or groups, sometimes by giving regu-

clarity to forms in themselves irregular, and always by giving unity to multitude and subordination of many objects to one, or to a few; and in all that relates to forms or to lines it is chiefly perspective that does these things. Linear perspective is, therefore, the basis of linear grouping, and until its laws were well understood composition remained imperfect, whatever beauties it occasionally put forth being accidentally obtained by the lucky chance of the correct copying of the appearances of nature, but with no certainty of repetition, the causes of the appearances not being understood.

The Proportions of the Great Pyramid.

The conclusion has been drawn from the angle of slope of the casing-stones discovered by Colonel Vyse that the builders of the Pyramid were acquainted with the ratio of the circumference of a circle to its diameter, a piece of knowledge they were desirous to embody in its dimensions. In fact, the slope of the original faces of the Pyramid comes out from Vyse's (or Perring's) measurement of the linear dimensions of these stones, $51^{\circ} 52' 15''$, and by Brettel's measure of their angle, $51^{\circ} 50'$, the mean of which differs only by a single second from the angle whose cotangent is the length of an arc of 45° of the circle, so as to make the whole periphery of the base all but mathematically equal to the circumference of a circle described with the height for a radius. So stated, the coincidence is certainly very striking. It by no means follows, however, that the ancient Egyptians were in possession of any calculus by which they could have arrived at a theoretical knowledge of the true ratio. It should be observed that the linear measures above mentioned are given only to entire inches, and those inches of a scale which may or may not have been verified with extreme precision, and therefore can lay no claim to minute accuracy. Computing, moreover, on these measures alone, the ratio of the periphery to the height comes out 6:2784, while that resulting from the direct measure of the angle is 6:2878, the true ratio being 6:2832. The individual results differ by 1-640th part of the whole quantity, and as we do not know with what instruments or what precautions the angle was measured, and it is given only to the nearest minute, it seems but reasonable to admit an equal proportional latitude of uncertainty in the original workmanship and in the numerical relation to which it was intended to conform. Now this is a very considerable approximation, much better than that of Archimedes a thousand years later. Still it would be easy for people in possession of such appliances as they must have had at command to ascertain the ratio in question to this or even to a greater degree of precision, by tracing, for instance, on a flat pavement a circle of 100 feet in diameter, and actually measuring the circumference. This they certainly might have done to the nearest 3-foot, which, on a length of 314 feet, would correspond to such a latitude of error. If aware of the importance of the problem, they might have gone much further. But, again, it by no means follows from anything which the dimensions of the Pyramid indicate, that they did possess a knowledge of the ratio of the circumference of a circle to its diameter, even approximately. By a very remarkable coincidence, which Taylor has the merit of having pointed out, the same slope, or one practically undistinguishable from it ($51^{\circ} 49' 46''$), belongs to a pyramid characterised by the property of having each of its faces equal to the square described upon its height. This is the characteristic relation which, Herodotus distinctly tells us, it was the intention of its builders that it should embody, and which we know now that it did embody, in a manner quite as creditable to their workmanship as the solution of such a problem was to their geometry. There is another, and a remarkable relation, viz. that the height of the Pyramid, including the casing, and measured from base to apex, supposed to terminate in a point, is one two hundred and seventy thousandth part (1-270000th) of the earth's circumference. Taking the equatorial circumference as unity, the error of this aliquot is one part in 736; but if the polar, only one in 3,506, the former error being in defect, the latter in excess, so that there exists somewhere or other on the globe a diametral section whose circumference is exactly 270,000 times the original height of the building. Though not a meridian, it is not very remote from one.

The Ostrich Feathers Badge.

The origin of the ostrich feathers as a badge of the Princes of Wales has been a matter of perplexity to antiquaries. Old Randall Holmes solved the difficulty in his summary way by asserting that they were the blazon on the war-banner of the ancient Britons. The only thing that in any way resembles the triple feathers in ancient British heraldry is to be found on the azure shield of arms of King Roderick Mawr, on which the tails of that monarch's three lions are seen coming between their legs and turning over their backs with the gentle fall of the tips, like the graceful bend of the feathers in the Prince's badge. The feathers themselves, however, do not appear in

connection with Princes of Wales until after the battle in which the blind King of Bohemia—too blind to read a manuscript, yet not so blind but he could see a foe within the swing of a battle-axe—lost his life. The crest of the Bohemian monarch was an eagle's wing. As for the motto of "Ich dien," it was assumed by the Prince to characterise his humility, in accordance with a fashion followed to a late period even by princesses—Elizabeth of York, for instance, took that of "Humble and reverent." Edward of Woodstock, therefore, did not adopt either the badge or the legend of the dead king of Bohemia; such is the conclusion at which nearly all persons who have examined into this difficult question have arrived. Nevertheless many have still faith in the old tradition as far as the badge is concerned. John, Count of Luxemburg, was the original style and title of him who was elected King of Bohemia, and fell so bravely and unnecessarily at Crecy. Now the ostrich feather was a distinction of Luxemburg, and it is from such origin that the Princes of Wales derive the graceful plumes which are their distinguishing badge but not their crest. This much is stated by Sir H. Nicolas in the "Archæologia," and Dr. D'Eyncourt suggests that the King of Bohemia's crest looks more like ostrich feathers than a vulture's wing. The question may be considered as having been set at rest by John de Arden. He was a physician contemporary with the Black Prince; and in a manuscript of his in the Sloane Collection Arden distinctly states that the Prince derived the feathers from the blind king.

Roman Architecture.

In spite of all the wonders of Greek sculpture, we must needs think that the Greeks had done little to fix the future architecture of the world. There was no elasticity or power of growth about the style. Right in its own country, used for the worship and aspirations which first gave it birth, it could not be used for anything else. But with the architecture of the men of the Roman name it was quite different. In the first place, they seized on the great invention of the arch, the most important invention to house-needing men that has been or can be made. They did not invent it themselves, of course, since it was known in ancient Egypt, and apparently not uncommon in brick-building Babylonia; but they were the first who used it otherwise than as an ugly necessity, and in so using it they settled what the architecture of civilisation must henceforward be. Nor was their architecture, stately as it was, any longer fit for nothing but a temple—a holy railing for the shrine or symbol of the god. It was fit for one purpose as for another—church, house, aqueduct, market-place, or castle; nor was it the style of one country or one climate. It would fit itself to north or south, snowstorm or sandstorm alike. Though pedants might make inflexible rules for its practice when it was dead or dying, when it was alive it did not bind itself too strictly to rule, but followed in its constructive part at least the law of nature—in short it was a new art, the great art of civilisation. True it is that what we have been saying of it applies to it as a style of building chiefly; in matters of ornament the arts of the conquered did completely take the conqueror captive, and not till the glory of Rome was waning, and its dominion become a tax-gathering machine, did it even begin to shake off the fetters of Greece; and still, through all those centuries, the Roman lords of the world thought the little timber god's house a holy form, and necessary to be impressed on all stately architecture. It is a matter of course that the part of the architectural ornament of the Romans shared fully in this slavery; it was altered, and somewhat spoiled Greek work, less refined and less forbearing. Great swinging scrolls, mostly formed of the acanthus foliage, not very various or delicate in their growth, mingled with heavy rolling flowers, form the main part of the designs that clove to the arts. There is no mystery in them, and little interest in their growth, though they are rich and handsome; indeed, they scarcely do grow at all—they are rather stuck together; for the real connected pattern, where one member grows naturally and necessarily out of another—where the whole thing is alive, as a real tree or flower is—all this is an invention of what followed Roman art, and is unknown both to the classical and the ancient world. Nevertheless, this invention, when it came, clothed its soul in a body which was chiefly formed of the Greco-Roman ornament, so that this splendid Roman scrollwork, though not very beautiful in itself, is the parent of very beautiful things. It is perhaps in the noble craft of mosaic—which is a special craft of the Roman name—that the foreshadowing of the new art is best seen. In the remains of this art we may note the growing formation of more mysterious and more connected, as well as freer and more naturalistic design; their colour, in spite often of the limitation forced on the workman by simple materials, is skilfully arranged and beautiful, and in short there is a sign in them of the coming of the wave of that great change which was to turn late Roman art, the last of the old, into Byzantine art, the first of the new.

NOTES AND COMMENTS.

IF the painting which Mr. SPENCE has discovered in the Pitti Palace can be proved to be the *Pallas* of BOTTICELLI, which VASARI mentions, the English artist will have accomplished a feat which will make foreign connoisseurs envious. VASARI relates how SANDRO executed several works in the Medici Palace for the elder LORENZO, especially a life-size figure of PALLAS on a shield wreathed with vine branches, from which flames are issuing. The picture escaped notice, which is not surprising, for BOTTICELLI'S style was long out of fashion. If it were considered valuable, it would hardly be allowed to drift into the Pitti Palace. Mr. SPENCE remembered VASARI'S description, although it does not correspond with the painting. He informed Signor RIDOLFI of his conclusions, which were confirmed by that authority. The goddess is represented as a young woman, partly in armour, with white robes over it. In one hand she holds a halberd, with the other she has seized a centaur by the hair, who has dropped his bow and appeals for mercy. The scene is on a plain near the sea. The painting may have an allegorical meaning, and relates to some action of LORENZO'S.

IN the "Account of Some of the Statues, Bas-reliefs, Drawings and Pictures in Italy," by the younger RICHARDSON, which appeared in 1722, he mentions "a range of little pictures" in one of the rooms of the palace of Mantua, and adds, "but the place is so dark that they are hardly visible." Were those pictures the frescoes by CORREGGIO which M. CHARLES YRIARTE claims to have discovered, and which he described on Saturday last before the Académie des Beaux-Arts? At any rate, his examination of them has persuaded the Italian Government to take more interest in the works, and they have been sufficiently cleaned to become visible. If RICHARDSON was not acquainted with them, to him at least the interest in CORREGGIO may be ascribed. No other connoisseur in the eighteenth century would have the courage to relate his sensations on entering a room in Rome in which pictures by CORREGGIO were hung:—"I do protest I never was so surprised, my heart struck against my breast. RAPHAEL is vastly great and sublime, and withal has a grace like that of the best of the ancients. But no master that ever was surprises like CORREGGIO; and yet without an equal measure of greatness, and with a grace not antique, nor like any other master. I cannot conceive or imagine how those expressions can be given that I see before my eyes, when I see at the same time perpetual incorrectnesses; not one of his pictures but has instances of this. CORREGGIO had a grace the pure effect of nature, not antique, nor like that of PARMEGGIANO, GUIDO, RAPHAEL or any other master, but something alone and which seems to be truly angelical." The RICHARDSONS could not be sparing in their praise whenever they admired an artist's work, and CORREGGIO was one of their idols.

IN noticing M. GABILLOT'S book on LEOPOLD ROBERT, we mentioned that the French painter was imprisoned on the recommendation of DAVID. A similar instance of DAVID'S manner of displaying his ill-will towards other artists is mentioned in the first volume of the "Journal of Marshal DE CASTELLANE," which is about to be published. During the Reign of Terror, HOUDON, the sculptor, was arrested through the influence of DAVID. Madame HOUDON at once appealed to BARÈRE to save her husband. The revolutionist was doubtful about the possibility of doing so, but he asked what was the work on which he was engaged, and which was the overt act of treason against the Republic? It was a statue of St. SCOLASTICA, who was represented as a handsome woman with a roll of paper in her hand. Just at that moment COLLOT D'HERBOIS, one of the most cruel and therefore most influential of the Conventionists, entered. BARÈRE informed him that HOUDON had completed a statue of Philosophy meditating upon the Revolution which deserved to be purchased by the Assembly and placed near the hall of meeting, and that the sculptor should be declared to have well served the country by his work. Through the interest of the two men that course was adopted and HOUDON escaped the guillotine. BARÈRE was a rabid

enemy of England, and MACAULAY did not exaggerate when he said of him, "BARÈRE approached nearer than any person mentioned in history and fiction, whether man or devil, to the idea of consummate and universal depravity." It is a little satisfaction to be able to record that a man who sounded all the depths of baseness was capable of doing a kindly action by rescuing one of DAVID'S victims.

THERE is no doubt much disaffection in Strassburg, but the German Government have undoubtedly endeavoured to do justice to the people, and the expenditure on building is unprecedented. A new Strassburg is arising, which from the number of educational buildings in it should become a rival of the famous universities. A few of the items which are under the consideration of the authorities will suggest at what price Strassburg is being made worthy of its position as a part of the empire. On the university buildings an expenditure of over 60,000*l.* will still be required. The new buildings of the Medical School will require a grant of 40,000*l.*, besides one of 8,000*l.* on subsidiary departments. About 1,000*l.* will also be expended on sculpture for one of the medical institutes. Every year a large outlay becomes necessary, and we doubt if it can all be derived from Alsatian revenues. All accounts are duly paid, and there is an immense amount of building to show for the money. The contrast between the young and the old Strassburg in consequence becomes every year more striking.

FROM its geographical position, Dublin would not appear to be a city that could not easily be drained. Although several Royal Commissions have considered the subject, the Liffey continues to be the sole resource. At last, however, an attempt is to be made to remove the main cause of the unhealthiness of Dublin. The Corporation on Monday approved of arrangements for commencing drainage works shortly. Three years ago it was settled that the sewage should be carried to the slob on the south side, near the Pigeon House Fort, and treated by a precipitating process. One obstacle was the probable effect of the works on the troops in the fort. The War Office considered the best course would be to sell the buildings to the Corporation. In 1813 the site of the fort cost 100,183*l.*, and besides 46 acres of land there are barracks, storehouses and other buildings. The Corporation offered 45,000*l.* for the property, but the War Office would not accept less than 65,000*l.*, and eventually it was agreed to pay that sum. The possession of the fort will enable the precipitating works to be constructed somewhat nearer to the city than was originally proposed, and there will be no necessity for any interference by the military authorities. Besides, the grounds and buildings can be utilised for several purposes. The cost of the drainage works is estimated at 302,000*l.* It is proposed to advertise for tenders as soon as possible, and the intercepting sewer will be first undertaken.

IF all Frenchmen resembled M. LACROIX, of Hastings, they would not be desirable clients for English architects. That gentleman, who was described as a man of means and position, availed himself of the services of Messrs. GANT & SLATTER, architects, when he decided on additions to his house. But his imagination produced visions of collusion between architects and builder. The work done, of course, appeared unsatisfactory and more costly than was equitable. The architects were compelled to recover their fees in the County Court. M. LACROIX then began a course of persecution of the senior of the firm. He wrote to various people in the district making charges against Mr. GANT, for which an action was taken that was concluded on Monday. M. LACROIX acted as his own counsel, and said that instead of paying he wanted 1,015*l.* as damages. The plaintiffs' counsel offered to discontinue the action if M. LACROIX would submit to an injunction, but the defendant would not agree. The manner of M. LACROIX was not likely to impress a jury favourably, and Mr. Justice HAWKINS was compelled to warn them that in their anger they must be careful about awarding damages that were too heavy. A sum of 250*l.* was given and an injunction was granted to restrain the defendant from repeating the libels.

SOCIETY OF ARCHITECTS.

THE fortnightly meeting of this Society took place on Tuesday evening, Mr. G. Highton, president, in the chair.

A paper, which was illustrated by numerous diagrams and plans exhibited on the walls, was read by Mr. R. Barry Parker, of Buxton, entitled

Some Principles Underlying Domestic Architecture.

Mr. PARKER, in the course of his address, said:—My appearance before you to-night is, I judge, somewhat the result of a conversation which I had with a member of this Society a few weeks ago respecting the lack of unity almost universally evident in our houses, and I suppose it is what I have to say as to the lines on which alone any mitigation of this fault is to be hoped for that you wish to hear from me to-night. I cannot but feel gratified that the Society of Architects should accord me this opportunity of laying before them the conclusions that my special training has caused me to arrive at; you will, I hope, pardon any seeming egotism in the way in which I shall do this, bearing in mind the necessarily definite position a lecturer must assume. In the class of house with which we are to deal to-night, there are so many directions in which improvement is needed, that it will only be possible for me, in the space of one lecture, to refer to a few of them, and to those specially which will illustrate most suggestively the main principles for which I contend. Suggestively, in the hope that some present will do me the honour to give further thought to what I shall touch upon, beyond what is possible to them during the length of time assigned to me this evening. The influences which our common everyday surroundings have upon our characters, our conceptions, our habits of thought and conduct, are often very much underrated; we do not realise the power they have of either aiding or hindering the development in us of the best or worst of which we are capable. Of the capacity the mere contour of a moulding has to bear the impression of refinement or vulgarity, we, as architects, are fully aware, but I think may not quite as fully realise the harmful influence of imperfect and unspontaneous drawing, or ill-conception in pattern, design, or ill-assorted combinations of colour; and perhaps the influence is none the less hurtful, in that it is often comparatively unconsciously operative on the recipient.

The thing of first consideration in designing a house is convenience, workability. The plan is that which should be first thought of, and in our small middle-class house one or two improvements seem to be wanted in planning. First of all, the most comfortable form of room for a sitting-room with respect to the relative positions of the door, windows and fire. The second best arrangement (when this cannot be got) is to have the door and fire both on the long wall. When the door is on the opposite wall to the fire you never feel to be able to get out of the draught of it, and of course this kind of thing is too palpably bad to need that anything should be said regarding it.

Well, here are four plans laid down on the lines usually adopted for this class of house. What are the chief defects? Are they not these? Too many rooms, and all therefore necessarily too small. In the larger middle-class house there are generally drawing-room, dining-room, library, kitchens and offices, all tolerably good rooms. Now, when a smaller house is wanted, the general custom seems to be to put exactly the same number of rooms, only reducing all in size. Would it not be far better to reduce the number of rooms, keeping such rooms as we do retain large enough to be healthy, comfortable and inhabitable?

Are not many of the houses we all know only too well most distressing in this respect, divided up as they are into a number of small compartments (we cannot call them rooms), all far too small to be healthy, too small to be really fit for human habitation. And what is gained by this cramping? Generally only that there are one or two of these compartments which are practically no good to anyone; in far the greater number of these houses the third room even is never used, or only used for the sake of it, and its chief advantage seems to be it is somewhere for the women of the household to put in any spare time they may have, cleaning down, dusting, &c.

Now many people have a feeling that there is a certain

cosiness in a small room entirely unattainable in a large one; this is a mistake altogether. Quite the reverse has been my experience, which is that such a sense of cosiness as can be got in the recesses of a large room, can never be reached in a small one, be it no larger than a sentry-box. But if your big room is to be comfortable it must have recesses.

There is a great charm in a room broken up in plan, when that slight feeling of mystery is given to it which arises when you cannot see the whole room from any one point in which you are likely to sit, when there is always something round the corner.

And what is made of the hall? Generally one of two things; either it is a passage with a kind of stepladder for a staircase and a hat-stand in it, with not room enough for you to hold the door and let a friend out, or it is a great bare, cold, comfortless waste space in the centre of the house, instead of being (as it might) the most comfortable and homely room, the centre of the common life of the household.

Of course a hall of this kind needs some care in planning. In the first place the staircase must occupy exactly that position in which it can be made an ornament and a pleasing feature in the room (all of which it is quite capable of being), and a position in which it does not detract from the cosiness or give any unpleasant feeling of draughtiness, or too great openness. In the second place the doors, necessarily opening into a hall, must be carefully so grouped that the parts of the room in which anyone would sit, should be out of the draught of them as far as possible.

In any house, all through the winter months, unless a fire of some kind is kept burning in the hall, the whole house is cold; most people find it necessary to have a stove or something, and in most houses it is thought necessary to have two other fires burning, that there may be somewhere to show visitors. Now, when the hall is also a sitting-room, we get for the trouble and expense of two fires all the advantages ordinarily attaching to three.

Here are three ground plans somewhat on these lines, but I want specially to call your attention to this:—Here, you see, we have a large hall, which is the principal sitting-room, one other good large room, kitchen, scullery and pantry on the ground floor. Just contrast, for a moment, the difference in appearance between these two halls: the one a comfortable room with a bright open fire burning, and the other, the ordinary hall, with a tile floor and a stove or the cramped passage.

I must now pass on to decoration and furniture. The best test of the artistic merits or demerits of a room, as a whole, is the impression it makes on one's entering for the first time. We can get accustomed to anything, and it is from this fact, taken in conjunction with what we have already noted of the power as an influence for advancement or degradation of beautiful or unbeautiful surroundings, that the importance of our subject to-night is partly drawn.

And what should be our feeling on entering a room? Simply this—How exquisitely comfortable! For the first essential in the form and design of any decorative object (and everything in a room should be a decorative object) is reposefulness.

I feel herein to be guilty of giving utterance to a truism, and I should hardly dare to state so obvious a fact were it not that I see this first principle so almost universally violated; for, if this test of reposefulness is the test, the average farmhouse kitchen has an artistic value far beyond that of ninety-nine out of every hundred drawing-rooms in the kingdom, and I will endeavour to show why. The first fault in our rooms which contributes to this end is over-decoration.

This is an almost universal failing. Everything has a pattern on it, and almost every pattern is mechanically produced, run out by the yard, and cut off just where it happens to be when the time comes for it to finish. No pattern bears any earthly relation to any other pattern, and the whole effect is fidgety, fussy and painful to a degree. Nothing is let alone, but every surface must needs be worried and tortured into some unwholesome form of mechanically produced and altogether soulless ornament. We cannot even find rest for our weary eyes on the ceiling, for tortuous intricacies of design meet them here also. Even this may be better than the staring white of old days, but that staring white had, at any rate, a very good excuse for its existence from utilitarian considerations. And observe (and this is the second fault I wish to refer to), all this ornament is made to shout, everything is clamouring for notice.

It would not be in place for me to say much here about those rooms in which any one element of decoration is in such flagrantly bad taste as to be noticed immediately on entering with a sort of start and feeling of "Oh, wall-paper!" or "Oh, carpet!" or whatever it may happen to be. (A designer will often aim at this for the sake of the advertisement, and at the sacrifice of his artistic principles.) But even when this extreme is not reached, everything seems trying (within certain limits) to assert itself, to attract attention.

Now any ornament you notice when you do not look for it,

or perhaps I might better say, when you do not wish to think of it, is necessarily in bad taste. The degree of assertiveness admissible in a decorative object is in direct ratio to the degree of its conventionalisation or naturalisation, or, to put it another way, to the degree in which it is fine or mechanical. For instance, we cannot pretend to regulate by rules of this kind pictures which are direct mirrors as far as possible of real things, though in so far as they claim to be mural decorations they come under this law.

Mr. Ruskin's wall, painted to look like a vinery, would admit of much more forcible treatment, being entirely painted by hand, and as true to nature as possible, than would a wall with a printed vine pattern on it, in which there necessarily was repetition. And natural flowers painted on the panel of a cabinet may fittingly be treated much more forcibly than would be admissible in a purely conventional design in a similar position, because natural flowers, hills and trees, cannot become assertive enough to influence one disquietingly; it is only when man's agency is called in that this element is introduced.

Therefore the more nearly approaching to nature the more assertive may be our ornament, or rather the less assertive it will be from this very reason, and therefore may be the more forcible in treatment. So we can stand in a conventional pattern design a degree of contrast in tones which we could not in a mere plaid or check, and in a plaid or check contrasts of tone which we could not tolerate in flat masses of colour. One of the chief underlying causes of this failing of fussiness we have noted is that a room is scarcely ever designed as a whole, never enough thought of as a whole.

The designer of each individual thing, knowing nothing of the form, or character of anything else in the room was going to take, thought only of his own design and worked enough interest into it to make it all-sufficient in itself, and the consequence (when his design gets put into a room in conjunction with a lot of other things, all designed in just the same spirit) is that restlessness, fussiness and fretfulness we have been deploring.

A room is a place in which to think of other things besides those relating exclusively to the room itself, and so much incident and interest should not be worked into it as to distractingly affect the pursuance of these thoughts and occupations. I say again, any ornament which you notice when you do not wish, is necessarily in bad taste. When choosing anything (a wall paper for instance), we forget that we are, while so doing, devoting all our thought and attention to the design we are considering, and that though pleasing under these circumstances, it may not be equally so to have by us when we wish to think of other things, or in the position for which we intend it.

Now no flat mechanical ornament designed to cover a large space should ever be so designed that you are able easily to trace the pattern at the other side of the room. Please do not understand from this that it should be small in design; far from it; things small in design are almost necessarily finikin, and therefore unreposeful, but being quiet and retiring in colour and contrast of tones, whether large or small, let it reveal (when you come to have leisure to examine it) vigorous broad and direct treatment, good, loving, thoughtful drawing, and real artistic conception and perception of beauty in form and line. How seldom we get these qualities, these examples, selected at random, will do something to illustrate. How laboured and unspontaneous they are, almost without exception, into what unwholesome forms the ornament is tortured, how the whole aim seems to be to make the design as restless and fussy as possible; a sort of feeling pervades the whole that the designer could not let the thing alone.

Here is one of the finest designs for a wall paper in the market; it is by Lewis F. Day. Here is this design, with a little spray running in among the main design. Could I have a better example of what I am endeavouring to show? Does not the spray largely destroy the repose of the whole, making it at once in some degree fussy? Of course Mr. Day, with his usual consummate skill, has introduced this additional interest in the way least calculated to destroy the unity. He did not, as many would have done, introduce some large flower form occurring at awkward intervals, thereby destroying the rhythm of the design; but still I think you will all feel with me that the introduction of this spray is only injurious to the whole composition.

I think we must not now go far into the faults in actual draughtsmanship most common in our designs. One thing is very striking, and this is, that almost without exception our designers seem out of their depth directly anything in the way of foreshortening is required of them; this cannot but lead us to the conclusion that drawing from nature does not form a sufficiently important part of their training; in fact I have myself known several men engaged entirely in drawing ornament who never drew a bud or twig from nature in their lives. However this may be, the fact remains that very few of our designers seem able to draw a leaf turning over with any truth or accuracy.

Another cause of failure in our rooms is the dread of repeating ourselves. With my wish that a more wholesome feeling in this may spring up among all engaged in artistic work, I am perhaps more anxious to have your sympathy than with anything which has gone before.

Let us, then, do nothing different from what we have done before until we feel it to be better than what we have done before.

Now this is no imaginary evil, but a very real and living one. How often do we all do something fresh, knowing it to be not the best we can do (best I mean more in kind than degree), simply from a weak dislike that people should say of us "He can only do this one thing." How often do we turn out a design for a certain purpose and position, knowing it to be not so good as one we have before done for a similar purpose and position, simply because we have not strength to do the best we can do, fearing people should think that is all we can do. In so doing we preclude all possibility of progress. Now observe this never occurs during the progress of any living act in the past. The man who had carved one Early English capital did not, when next he had a capital to carve, say, "I know nothing more beautiful, but I must at any rate do something different; I must not put the same capital here again." On the contrary, his aim was to carve the same capital again, only he saw some little point in which he could improve on the last he did, some way in which he could mass his light and shade so as to give them a more pleasing form when seen at a distance, or some more lovely feeling he saw it possible to introduce into the reveal of a leaf or the curve of a stem.

You must forgive me if I dwell on this a little, as with all of us who have any hope or wish to see a living art again existent among us, that we should realise the full significance of this is of vital importance. There are many other changes which must take place in our practice of the arts, and these very radical changes, before living art is again possible to us, but if I can bring home to any one, directly or indirectly, the full significance of this, I shall have done something towards this great end.

The reply many would make to this is:—"This aiming at change, variety, novelty, &c, is demanded of the designer by a capricious, change-loving public, broadly speaking, incapable of any true judgment or appreciation of good and bad in art."

In reply to this I think we cannot do better than call to recollection what Mr. Ruskin says on this head. "You may like making money exceedingly, but if it come to a fair question whether you are to make 500% less by this business or to spoil your building, and you choose to spoil your building, there is an end of you. So you may be as thirsty for fame as a cricket is for cream, but if it come to a fair question, whether you are to please the mob or do the thing as you know it ought to be done, and you can't do both and choose to please the mob, it's all over with you, there's no hope for you; nothing that you can do will ever be worth a man's glance as he passes by."

The fourth cause of failure in decorating and furnishing is virtually the same as we noticed when speaking of planning. When a small middle-class house was wanted, what was usually done, we saw, was virtually to take a plan suitable for a larger house and reduce it every way, instead of designing a house suited to the new requirements. This same mistake is generally made in the decoration and furniture; instead of these being designed to suit the conditions of circumstances in which they are to be placed, each designed for its position and purpose, and good and honest as far as it goes, what do we find? Cheapened imitations of the sort of thing found in the larger house, cheapened by being badly made, by cast ornament instead of wrought, by veneer on pine instead of solid wood, by cast metals made to look like wrought, by machine-carved wood, by marbled slate, &c.

And now for the fifth and the last cause of the failure of which I shall speak, and this is, the very marked feeling which everything has of not having been designed for its place, the look everything has of being ready to move at any moment. Most things to look right and happy in their places must be designed for their places. The advantages attaching to a room furnished in this way and largely by means of fixtures, I think the accompanying sketches will do something to illustrate. Here are the two views again of the hall in the house of which we saw the plan and elevations a while ago.

There is a unity, completeness, comfort and repose about such a room which can never be got in a room in which the furniture, &c., is not designed for its positions and looking at home in its positions and not just temporarily stuck where it happens to stand, with a look of being on the alert and ready to move on at a moment's notice. This design for a drawing-room is by no means bad, it is at any rate a long way above the average, but it illustrates what we are noticing.

But it is time to sum up our position and note the general conclusions to which we are led. I have described some of the defects we most commonly see in planning and the arrange

ment of the hall, the entire want of reposefulness (that infallible criterion of good ornament) that troubles the man of taste in nearly all domestic decorative work, and the lack of fitness in the furniture that is generally crowded into the rooms of smaller middle-class houses, which adds the final touches to the complete failure, from an artistic point of view, of the great majority of such rooms.

I further mentioned as causes generally contributing to this failure, over-decoration, the covering of all surfaces with a mass of incongruous patterns quite fatal, even where the designs are in themselves good. The effortfulness of most ornament by which every pattern seems to clamour for notice, in which connection I stated as a guiding principle that any ornament you notice before you look for it, is likely to be in bad taste. Further, I noticed the laboured and unspontaneous character of so many of the designs themselves and the lack of good drawing in them, and hinted that this arose partly from the designer's dread of repeating himself and his eagerness to produce something fresh without considering whether it was better. Finally, I drew attention to the way in which so many rooms are furnished with cheap imitations of better (or more esteemed) materials, decorated with cast or otherwise mechanically produced imitations of hand-wrought ornament, and the general unfitness and ready-to-move look which results from there being no fixed furniture, but all having been designed without any thought of the room, and the room planned without any view to its furniture.

I have several times hinted that the entire lack of unity, which is the inevitable result of all this, must continue so long as our rooms and our houses are never thought out as a whole, so long as one man plans the building, another arranges the decorations, and a third picks up the furniture of twenty designers here and there and everywhere. It is essential to any good result that one man should design the house as a whole. I do not mean necessarily that he should design everything in it, or draw with his own hand every detail; but he must exercise a controlling power, selecting where he does not design, and insuring that the work of all may be done in a spirit of co-operation towards the complete whole which he planned.

You will all be wishing to ask me, I doubt not, how this is possible in our days of speculative building, short leases and shorter tenancies. I must at once admit that to a large part of this work such a system is inapplicable, though even here much could be done if each department made what improvements are possible, irrespective of the others. The lack of power to control the decorations does not excuse a badly planned hall. But outside the purely speculative building there is yet a large amount of work to which the system is applicable, in greater or less degree, such degree mainly depending on our clients, and here we have the real difficulty. We are powerless to compel our clients, nay, to a large extent, the client has a right to have his own way.

I suppose a doctor is in a similar fix. He is called in to prescribe for a patient, and finds his prescription is useless because the patient will continue to smoke. He does not (if he is worth anything) accept the situation, but he explains that smoking is in this case fatal; that it renders all his skill unavailing, and if all his advice is neglected, he will finally refuse to act.

Architecture is rightly called a profession only when the architect advises his client what is best, and brings the whole weight of his knowledge and experience to persuade him from anything foolish or in bad taste. When he produces to order some plan of which he cannot approve, he is merely a merchant of plans.

While speaking of this duty of the architect's, I would not be thought to make light of many conditions of modern life, which will so long as they continue, and to the extent to which they spread, hinder all attempts to produce beautiful and dignified homes. One such condition is the instability of social position; everyone is seeking to get a step further up the social ladder. The result is a demand for houses which look as though they belonged to the next social grade above that of the people who are to live in them. To such untrue aims art refuses any countenance, and it is well.

But there is an already great, and daily increasing, number of those who are weary of this fruitless struggle of a life spent in work entirely without interest or beauty, or the power of giving a vestige of real pleasure, that they may have the means to acquire things without interest, beauty, or the power of giving any pleasure, beyond the sordid satisfaction of letting Mr. and Mrs. So-and-so see they can afford to have them. These are anxious to find houses suited to their genuine wants, simpler even, in many cases, than the one I have shown you, houses in which the work will be reduced to a minimum, and the beauty increased to a maximum, by the only true method of making all the useful and necessary things beautiful, not by the false method of keeping all useful and necessary things out of sight, trying to conceal their purpose, or to appear unconscious of their existence and substituting for them things recognised to

be useless, but regarded (so long as the fashion lasts, at any rate) as beautiful.

This polished mahogany life of ours, with stucco trimmings and jerry joints presented for view to our visitors and acquaintances in the front room, is not, I believe, what many of us really want; we are tired also of the dismal and cramped, but at any rate real, back office, back room and kitchen life, and many are looking for houses and for architects who will design them houses in which they shall not spend their labour for that which is not bread, but shall be able to live a life of less artificiality than our present complex nineteenth-century existence, a truer healthier life altogether.

I have just said that the true method of making a room beautiful is to make all the necessary and useful things in it beautiful; so much is this true that it becomes almost impossible to design a really beautiful room that is to have no useful work done in it and natural life lived in it. An architect called upon to design a room in which nothing more earnest is to be done than to gossip over afternoon tea, has indeed a sad job. For a room must always derive its dignity or meanness, and reflect somewhat the character and kind of occupation which is carried on in it.

For instance, the studio of an artist, the study of a man of letters, the workshop of a carpenter, or the kitchen of a farmhouse, each in its position and degree, derives a dignity and interest from the work done in it. And the things in the room bear some relation to that work, and will be the furniture and surroundings natural to it, as the bench and tools in the carpenter's shop, the easels and canvases in the studio, and the books and papers in the study, and the bright pans and crockery in the kitchen. All these lend an interest and a sense of active, useful human life to the room which redeem it from vulgarity, though it be the simplest possible, and no amount of decoration or ornamentation can give dignity or homeliness to a room which is used as a showroom, or in which no regular useful life is lived.

For in the work-room all things have a place by reason of their usefulness, which gives a sense of fitness and repose entirely wanting in a room where a place has obviously had to be found for everything, as in a drawing-room. How far things, beautiful alone, are to be allowed place in our rooms I am not prepared to say.

Thoreau, you will remember, threw away the fossil, the only ornament in his room, because it required dusting. While not suggesting that we should follow his example to such an extreme, I yet think that in retaining his spade and his axe he retained more of true decoration. And I believe in the main that the more adapted to its use anything is, the more graceful will it be in shape. The bent handle of the axe, more comfortable to hold, is also more beautiful than the straight, and in the degree the curve and form of the handle is adapted to its uses as an axe, by just so much the more beautiful it becomes.

The charm of the farmhouse kitchen, with everything in its place because of its usefulness, can of course be increased to an unlimited extent by making all the useful articles also beautiful in form and harmonious in colour. This is the line on which alone, I contend, a really beautiful room is to be got, and I would discourage all attempts at adornment by finding places for useless things.

I am glad to think that, owing to the great increase of education and employment among ladies, there will be less and less call for the old-fashioned drawing-room; ladies will want a room to work in, not to dawdle in.

Pardon me if I seem to have dwelt over long on some of these difficulties in the way of designing really beautiful rooms. I have done so in the belief that they do not, as at first may appear, lie outside our province. For I believe, as professional men, we have just such power of influencing our clients, by helping them towards a more natural life, as the doctor has in such matters as diet; and particularly is this power evident in the domestic branch of the profession with which we are dealing.

In building a man's shell for him we certainly can influence very largely the life he will live within it; and while it is our duty to make that shell fit the life as well as possible, it is surely also our privilege to make it conduce to the realisation of the best of which he is capable.

In so far as we do this, we shall rise above the mere planner of houses, and take our places in the work of planning and moulding the future life of the people.

A vote of thanks, proposed by Mr. G. A. Middleton and seconded by Mr. S. Marsland, was passed by acclamation to Mr. Parker.

Mr. Grainger Helton has been asked to complete plans for the restoration of St. John's Church, Perth, showing alternatively the throwing of the east and middle churches into one, and the improvement of the middle church on the footing of the churches remaining separate.

CHRISTIANITY IN CHESHIRE.*

THE district embraced within the diocese of Chester, as formed by Henry VIII., was occupied at the time of the Roman invasion by two distinct Celtic tribes—the Cornavii, who were settled in the present Cheshire, and a much more numerous and powerful people, the Brigantes, who held Lancashire, Westmorland and Cumberland, as well as a considerable portion of Yorkshire. Their religion was of the polytheistic type, with an admixture of Druidism; but no other traces remain of their worship than an occasional *maenhir* or long stone (which has been subsequently, in all probability, converted into a Christian emblem), some cup and circular markings, and a few local names such as Belisama (the name of the Ribble), and Aerven, the Goddess of War (an early name for the Dee). The Roman remains which have been discovered from time to time at Chester, Manchester and other military stations in this district afford no indications of the prevalence of Christianity. None of the inscriptions on the tombstones of the legionaries bear the record of any Christian hope. Many of these inscriptions preserve touching reference to the deep affection subsisting between wife and husband, mother and child, master and slave; but all are dedicated *dis manibus* to “the Gods of the shades.” The altars, of which no less than twelve have been found at Chester, are inscribed with names either (1) of the deities of Roman mythology—Jupiter, Optimus Maximus, Tanarus, a Welsh form of Tonans, the thunderer, Mars Conservator, Minerva, Esculapius, the genius of the place, or of the Emperor, the nymphs and fountains—or (2) they are dedicated to the *Deæ matres*, to whom several altars have been found in Belgic Gaul and along the banks of the Rhine. I am not forgetting the so-called ecclesiastical stone, which I believe to be that of a Roman matron and her attendant. There are in the Chester Museum two or three relics of Mithraic worship, but no dedications, as at Carlisle, to those gods with strange uncouth names, supposed to be the deities worshipped by the Brythonic Celts, such as Belatin castor (which recalls the Phœnician Baal), Maponus, Setlocenia, Coventina (goddess of memory), and the like. It is not, however, to be assumed that the Christian faith was not taught in Cheshire and Lancashire during the period of the Roman occupation. The two legions (20th and 2nd pia adjutrix) which, like Roman soldiers in other parts of the empire, were important heralds of the Prince of Peace, must have had among them more than one who had some knowledge of the Gospel message. But it is more than doubtful whether this saving knowledge radiated to any distance beyond the military stations.

The villas and other remains which have been discovered are usually close to the great centres of population, showing that the Romans made no attempt to spread their influence outside a certain area. The rest of the land—often a dreary succession of fen and morass, varied with long tracts of unreclaimed forest—was left to the older inhabitants, who for the most part would keep aloof from the Roman camp and the great highways, and did not therefore come under Roman influence, whether for ordinary civilisation or for religious teaching. There must, however, have been exceptions to this. It happened not infrequently, if we may judge from sepulchral inscriptions, that the legionary soldiers intermarried with the natives, and on the completion of their term of service settled down permanently on the lands assigned them. Whether this leavening had a Christian tendency cannot be ascertained. It is worth notice in this connection that the tonsure, which was one of the points of difference between the Celtic and the Roman Church, as practised in Britain and Ireland, is said to be a survival of a Druidic fashion.

We must pass over a long interval of years after the final withdrawal of the 20th Legion from Chester (about 410 A.D.), before we come to any definite statement in connection with the religious condition of the district. Alleluia victory of Germanus, near Mold, occurred in 430 A.D., and must have borne some fruit at least in the neighbourhood of Chester, if not throughout the district. In the story of the struggle between the Britons and the Saxons under Æthelfrith, which culminated in the so-called Battle of Chester in 613, the monks of Bangor Monachorum or Iscoed play an important part. This place, now a small village on the borders of Cheshire and Shropshire, called by Bede Bancornberg, is identified by some writers with Bovium, a station on the great Roman road between Chester and Wroxeter. The names of three of its gates are still preserved—Porth Hwgan on the north-west, Porth Clais on the south, and High on the east. (E. Llwyd, writing 1699, says the fourth gate was in Dwngre.) A monastic establishment of some importance was in existence here before the arrival of the Italian Mission under Augustine (A.D. 596).

A tradition declares that Pelagius (Morgan, the sea-born), who was born A.D. 350, belonged to this house. The community must have been in a flourishing condition to have been able to send a detachment to Bangor Vawr, in Carnarvonshire, in 516, as well as another four years later to Bangor, in Ireland. It was the last Abbot Dunaud, or Dinnoth, who, with seven British bishops, met Augustine in conference, and, with the traditional spirit of independence, refused to accept his supremacy or adopt his suggestions. Augustine, angered at the repulse, retorted that if they would not preach the gospel to the Saxons as brethren, they must not be surprised if they were slain by them as enemies—words which, in the light of subsequent events, were regarded as a prophecy, some even going so far as to suggest that Æthelfrith, of Northumbria, was instigated by Augustine, in revenge, to attack the monks. At that time this monastery was one of the largest in Britain, consisting (according to Bede, who lived in the century that witnessed the destruction of the monastery) of at least 2,100 monks, that is, seven bodies of 300 each. Bede relates how on the advance of Æthelfrith upon Chester in 613, the monks of Bangor, anxious for the success of their fellow-countrymen, after a three days' fast sent forth 1,200 of their brethren, who made their way to the battle-field and there offered up prayers for victory to their nation. Æthelfrith watched the wild gestures of the monks as they stood apart from the host with arms outstretched in prayer, and bade his men attack them first of all. “Bear they arms or no,” said the king, “they fight against us when they cry against us to their God.” The slaughter was so complete that only fifty escaped, the Welsh chieftain Brochmael, who had undertaken to protect them, having basely deserted them. This has been called the Battle of Chester, and it is stated by more than one writer that the massacre of the monks took place under the walls of Chester. But it is more probable that the scene of the tragedy should be placed nearer to the monastery at Caergwile, or, with still greater probability, at Holt, which position on the Dee opposite Farndon bears in documents as late as the Elizabethan period the alternative name of *Castrum Leonum* (castle of lions), the seal bearing a lion rampant. Local names along what would be the line of march between Bangor and Chester still preserve the memory of a terrible disaster to the British arms. Among these may be mentioned *Maes yr Ing*, the “Field of Agony,” near Worthenbury, and *Bryn Yockin* (*yr ochain*, the “Hill of Groaning”), near Rossett. The faith of Woden and Thor might appear for the time to have triumphed over the religion of the Crucified One. The heathen Saxon might have had some apparent justification for taunting the British Christians with the derisive question, “Where is now thy God?”

The great monastery was rased to the ground. This would be no great task, for the monastic buildings of the Celtic Christians were of the simplest possible character, no such elaborate structures as William of Malmesbury, who confounds it with Bangor in Carnarvonshire, evolves apparently out of his own imagination. He says:—“No place could show greater remains of half-demolished churches and multitude of other ruins.” In fact it was simply constructed of wattle-work, *i.e.* osiers interwoven and plastered over, and leaving but little trace of their destruction. But the spiritual influence of the faithful occupants of this monastery did not pass away with the destruction of their corporate home. It extended to other and far distant districts. Not only had they sent forth a number of brethren to settle in Bangor or Benchor in Ireland, but Deiniol Wyn, the son of Dunawd, the last abbot of Bangor-is-Coed, founded a church at Hawarden still dedicated to him (St. Deiniols), and established a monastery at Bangor Vawr in Carnarvonshire, and later was appointed by the British king, Maelgwn Gwynedd, the first Bishop of Bangor. It was Eurgain, the saintly daughter of this same Maelgwn Gwynedd, who founded the church of Northop, a few miles from Hawarden, which preserves in its Welsh form the name of the foundress, *Llaneurgain*, and we cannot doubt that holy men and women would endeavour to make their influence felt at so important a centre as Chester. The British Christians have been censured for their refusal to take their part with Augustine in preaching the Gospel to the heathen Saxons. It must be remembered that the Britons were engaged in a life and death struggle with the Saxon invaders for the possession of their native land, and that they were being thrust further and further back into the corners of the island. Such a time of bitter anguish and hard fighting was certainly not favourable for the preaching and hearing of the gospel of peace as regards either the conquering or the conquered race. But, as we have seen, the British Christians did not neglect the duty of evangelisation in the districts which still remained to them.

It has been suggested that Christianity was first preached to Britons in the peninsula of the Wirral by Cyndeyrn or Kentigern in 560, about the time when, passing from Strathclyde, on the coast of Lancashire, to North Wales, he founded the monastery at Llanelwy or St. Asaph, and that the holy man he left there as its first bishop in 573, St. Asaph, tended the infant

* A paper by the Rev. Canon Morris, D.D., read at the fourth meeting of the session of the Chester and North Wales Archæological and Historic Society, and published in the *Cheshire Observer*.

church in Wirral. If this very probable suggestion is accepted it establishes one more bond of union between the Church of England in England and Wales. The same writer goes on to show that after the Battle of Chester in 613, the British remnant left in Wirral remained Christian, but hated by the English, and hating in return, made no attempt to convert their conquerors. The later conversion of the English is to be attributed to St. Aidan or St. Chad. The work was not left entirely, however, to ecclesiastics. It is remarkable that hardly forty years after the light of Christian truth had been apparently extinguished by Æthelfrith's destruction of the monastery at Bangor-Iscoed, Penda, "the strong," the impersonation of the power of heathendom in middle England, before whom the saintly Oswald and four other kings had fallen, was to find his own daughter and one of his sons allied to those who professed the faith he so bitterly opposed, while another son, Wulfhere, and his granddaughter, Werburga, were to have their names associated to all time with the evangelisation of Mercia, as royal nursing father and nursing mother of the Church in that important district. The story of their work and of Oswald, the Christian son of the heathen Æthelfrith, has been told elsewhere.

There only remains to be added some details specially relating to Cheshire and Lancashire. Some at least of the early Christian monuments which have been found in these counties bear silent testimony to the great religious revival which went on there in the seventh century. The greater number of the crosses and monuments cannot be earlier than the ninth century, some belonging to the eleventh century. And it is doubtful whether the local tradition about the Sandbach crosses, that they were erected to commemorate the conversion of Penda, Penda's son, to Christianity in 653, is to be accepted unhesitatingly. Whether these Sandbach crosses belong to this early date or are to be referred to the next century, they preserve a most interesting group of Christian subjects, probably the finest in all England. The several panels include the following scenes:—The crucifixion, with the sun and the moon above and St. Mary and St. John below, surrounded by the symbols of the four evangelists; the Nativity, with the ox and the ass kneeling before the holy child in the manger cradle; the Virgin enthroned, holding the holy child, with a saint on either side and the holy dove above; Christ in glory, with an angel on the left and St. Peter carrying the key on the right; Christ led bound before Pilate; Christ carrying the cross. Another important cross, much weathered, at Halton, in Lancashire, curiously illustrates the existence at the time of Paganism side by side with Christianity. On the east and north faces are scenes from the Scandinavian mythology, representing Sigurd roasting the heart of the dragon Fafni on a spit, his horse Grani returning home riderless after his master's death; Regin, the dwarf smith, working at his forge. On the opposite face among other Christian subjects is to be seen Christ enthroned, with two smaller figures clasping his feet. It is one more instance, I believe, of the appropriation by Christians of heathen monuments. Again, the sculpture on the cross at Winwick in Lancashire has been supposed by competent authorities (Canon Browne) to refer to St. Oswald, to whom the church at Winwick is dedicated, one panel representing his dismemberment after his defeat by Penda, while the other shows water being carried from St. Oswald's Well, which is a short distance from the church. The rest of the early Christian monuments in Cheshire and Lancashire found at Neston, Bromborough, Hilbre, West Kirby, Overchurch, in the Wirral peninsula; Chester, Macclesfield, Lyme Park, in Cheshire; Bolton, Heysham, Whalley and Lancaster, in Lancashire, are of much later date.

No remains exist of any Saxon churches in these counties. The earlier churches were certainly built of wood or wattle. Stow, in his survey of land, has made a curious slip in speaking of the Wirral. "These Saxons were likewise ignorant of building with stone till the year 680, for then it is affirmed that Benet, abbot of Wirral, master to the Venerable Bede, first brought artificers of stone houses and glass windows into this island amongst the Saxons, arts before that time to them unknown, and therefore used they but wooden buildings." Stow is referring to Benedict Biscop, who was of Wearmouth, not of Wirral. However other parts of Cheshire may have fared, it is certain that the Wirral peninsula suffered most severely from the invasion of the Northmen, an invasion the memory of which abides in the Norse names, preserved so markedly here as compared with the neighbouring districts. While the Christianising influence of the British settlers has left no other trace than such names as Landican, Poulton, Lancelyn, the numerous villages with the termination "by" point to the Norse immigration. Such are Whitby, Kirkby, Frankby, Greasby, Pensby and Irby. Not more than 300 years had elapsed after the triumph of the Saxons when the Saxons themselves had to suffer in turn the miseries they had inflicted on the Britons—to see their fair fields ravaged, their towns sacked and burnt, their churches and monasteries ruth-

lessly destroyed. It was in 1000 that King Ethelred's fleet mustered at Chester, and thence proceeded against the Viking rovers, who were sweeping the western waters and carrying off their valuable spoils from the mainland. And it was most probably a little before that time that the wave of heathenism swept over Wirral. But the Norsemen did not long remain in heathen darkness. They submitted to learn the religion of the English, and hence with Thurstanton, which recalls the name of the god Thor, we find also West Kirby, as well as Kirby-in-Wallasey. In the Litany of the period we are discussing, one of the suffrages was, "Deliver us, O Lord, from the terror of the Northmen." The terror of these Northmen had at an early period, in 875, forced the nuns to transfer the revered body of St. Werburgh from Hanbury to the safe keeping of Chester. But Chester itself suffered later from these ruthless invaders, and the nunnery, which had been founded to watch over the sainted remains, after unhappy experiences, was re-edified by Ethelfleda, the "Lady of the Mercians," for secular canons, and later endowed more amply by King Edgar, who, by a charter dated 958, granted to it certain lands. A century later, 1057, the buildings were extensively repaired by Leofric, of Mercia, who bestowed upon the community additional privileges.

When Domesday was compiled, the canons are stated to hold, besides hides in several hundreds of Cheshire, thirteen houses in Chester itself, free of tax, one for the warden or head of the community, the rest for the canons. These were in turn ejected by Hugh Lupus in 1093, when he established in their stead an abbot and convent of the Benedictine rule. Chester could boast of a much older building in St. John's-without-the-Walls, if the tradition which ascribes its foundation to King Ethelred, in 689, has any ground of truth. St. John's was the scene of the great pageant when it was visited in solemn pomp and ceremony by King Edgar the Peacegiver, in 960, in his imperial progress round Britain, after being rowed from his palace on the Dee by the eight vassal kings who there did homage to him. St. John's, too, was repaired and enriched by Leofric of Mercia, and still later became the cathedral of Peter, the first Norman bishop of Mercia, who built the nave and tower piers. Some few miles away in the same county, but several years earlier, in a solitary swampy district, another bishop had taken refuge from the marauding Danes—Plegmund, Alfred's archbishop, who has given his name to Plegmundstall. The dedication of a church in Chester to St. Olave points to a settlement of Danes at Chester itself. This church stands, as might be expected for a church built by the roving Dane, not far from the river bank and outside what has been considered by some to be the line of the original Roman wall before the circuit of the city was extended by Ethelfleda. A list of ancient dedications which throw light upon the early establishment of Christianity in Cheshire—St. Leonard, at Warmingham and Taxal; St. Helen, at Tarporley, Witton; St. Bridget, at West Kirby and Chester; St. Martin, Chester; St. Oswald, Bidston, Blackford, Chester, Peover Lower, Malpas, Worleston, Brereton; St. Hilary, Wallasey; St. Wilfred, Grappenhall, Davenham, Mobberley, Northenden; St. Boniface, Bunbury; St. Chad, Farndon, Tushingham, Over, Wybunbury, Chadkirk, Handforth; St. Edith, Shocklach; St. Alban, Tattenhall; St. David, Wettenhall; St. Lawrence, Frodsham, Over Peover, Alderley, Stoak; St. Werburgh, Warburton and Chester.

THE TRIBUNAL OF APPEAL.

THE following regulations as to the procedure to be followed in cases of appeal and the fees to be paid under the new Building Act have been made by the Tribunal, and approved by the Lord Chancellor in accordance with Section 184:—

All communications shall be written, type-written, or printed on foolscap paper.

All drawings shall be on tracing linen and in duplicate.

Any further drawings or copies of drawings shall (if so required by the Tribunal) be supplied by the appellant.

Appeals shall be addressed to the Tribunal of Appeal and shall be lodged and the fee thereon shall be paid at the office of the Tribunal, No. 13A Great George Street, Westminster, S.W., by hand, within the period (if any) prescribed by the Act; and where no period is so prescribed, within fourteen days after notice of the decision, determination, certificate, requirement, or regulation appealed against has been given to or served on the appellant.

The appeal, which shall specify the section and subsection under which it is made, shall be accompanied by copies of the original application and of the decision, determination, certificate, requirement, or regulation appealed against, with copies in duplicate on tracing linen of all plans or drawings relating thereto. These documents shall be supplemented by a short statement of the facts, setting out the grounds of the appeal, together with a list of the names and addresses of all parties to

whom notices under the original application and of this appeal have been given.

The appellant shall also within the time limited for lodging the appeal give notice of such appeal to the London County Council, and in cases where the original applicant is not the appellant, to such applicant, and in case of an appeal under any of the following sections also to the persons mentioned opposite such section.

Section.	With Reference to.	Persons to whom Notice to be given.
5 (8)	The superintending architect's determination as to the level of the ground.	The superintending architect.
13 (3)	The Council's determination that the prescribed distance shall be greater than 20 feet from the centre of the roadway.	The district surveyor. The local authority.
13 (4)	The Council's consent to the erection, &c., of any building, &c., at a distance less than the prescribed distance from the centre of the roadway.	The local authority. The owners and occupiers of the nearest building on each side of the proposed building.
19	The refusal or conditional grant of Council's sanction under Part II. to streets.	The local authority.
19	The refusal by a district surveyor of his certificate to plans of a building or structure to be altered or re-erected under Section 13.	The district surveyor. The local authority.
25	The certificate of superintending architect as to general line of buildings.	The superintending architect. The local authority and all other persons entitled under Section 24 to notice of the superintending architect's certificate.
29	The certificate of the superintending architect determining in what street or streets a building or structure is situate.	The superintending architect. The local authority and all other persons entitled to notice of the superintending architect's certificate.
43 (i) & (iii)	The refusal of a district surveyor to certify plans.	The district surveyor.
44	The Council's determination in cases where a person desires to rearrange a cleared area.	The local authority.
46	The superintending architect's certificate determining the front and rear of a building.	The superintending architect.
48 (2b) & (4)	The Council's refusal to allow a building to be erected to a greater than the prescribed height.	Such owners or lessees as the Council may under this section direct.
78	The district surveyor's requirement respecting the construction of public buildings in case of disagreement.	The district surveyor.
79	The district surveyor's requirement respecting the conversion of any building into a public building in case of disagreement.	The district surveyor.
122	The Council's refusal to permit, or any of the Council's regulations as to, or the decision of their engineer, or conditions imposed on the Council's grant of a license for the erection of dwelling-houses on low-lying land.	The Council's engineer. The local authority.
132	The refusal of a district surveyor to grant a certificate as to sky-signs.	The district surveyor.

All documents lodged with an appeal shall remain deposited in the office of the Tribunal as records of the case.

After the lodgment of an appeal the earliest convenient appointment shall be arranged for the hearing of the appeal, and shall be communicated to the parties by letter. The fees in respect of the view (if any), the hearing and order shall be paid by the appellant before the hearing.

Appeals shall be heard at such place as the Tribunal may from time to time determine.

The hearing of appeals shall be open to the public.

The full Tribunal of three members shall sit to hear appeals.

The London County Council and the parties interested

may appear before the Tribunal either in person or by counsel, solicitor, or agent, and the procedure at the hearing shall, subject to such variations as the Tribunal may think fit, be similar *mutatis mutandis* to that adopted on the trial of actions before the High Court, thus:—

Preliminary objections, if any, to be heard and disposed of. Appellant to state his case and call his witnesses.

Respondent to state his case and call his witnesses.

Any other parties interested to be heard.

Appellant to reply.

The decision of the Tribunal shall be embodied in an order in writing under the seal of the Tribunal.

The original order and all documents relating thereto shall be filed and preserved in the office of the Tribunal.

Office copies, under the seal of the Tribunal, of orders and other documents shall be upon payment supplied to any party to an appeal, and shall be admissible in evidence for all purposes of the Act, and regulations to the same extent as the original would be admissible. All copies of orders or other documents appearing to be sealed with the said seal shall be deemed to be office copies without further proof.

The file of documents shall be open to inspection by any person at the office of the Tribunal between the hours of 11 and 3.

The fees to be paid to the Tribunal by the appellants and other parties are as follows:—

	Higher Scale.*	Lower Scale.†
	£ s. d.	£ s. d.
Lodging appeal	2 0 0	1 0 0
View	2 0 0	1 0 0
Hearing	5 0 0	2 0 0
Order	2 0 0	1 0 0
Stating special case	2 0 0	1 0 0
Inspection of an order	0 1 0	0 1 0
Inspection of file of proceedings	0 2 6	0 2 6

Office copies, 6d. per folio. Plans, &c., according to work involved.

Copies other than office copies, 4d. per folio. Plans, &c., according to work involved.

The preceding regulations as to procedure and fees to be paid were made by the Tribunal of Appeal in accordance with the London Building Act, 1894, section 184. This 21st day of February, 1895.

For and on behalf of the Tribunal, ARTHUR CATES,
Chairman of the Tribunal.

Approved: HERSCHELL, C.

March 1, 1895.

THE GLASGOW SCHOOL OF ART.

A MEMORIAL has been sent by the Governors of the Glasgow School of Art to the Lord Provost and members of the Town Council seeking for aid to erect a new school, for which the Bellahouston Trustees have offered a site costing 6,000*l.* and a cash grant of 4,000*l.* It states:—

The Glasgow School of Art occupies premises in the Corporation Buildings, Sauchiehall Street, at an annual rent of 200*l.* The accommodation is limited and is not well adapted for the advanced instruction which is given.

When the art gallery and museum scheme was proposed, a School of Art was also projected as part of the scheme, and architects were asked to include the necessary accommodation in their drawings. The accepted designs contained provision for a School of Art.

Some of the subscribers to the Art Gallery and Museum Fund gave their subscriptions on the understanding that a School of Art was to be provided in the proposed buildings.

The Parks and Galleries Trustees, however, found that administrative difficulties might arise between the Corporation and governors of the School of Art as joint but independent occupiers of the same building, and a deputation from the school having met a committee of the Parks and Galleries Trust, the whole matter was discussed, and it was finally minuted that the Parks and Galleries Trustees "as from the time when the new buildings are ready for occupation should during their pleasure allow the School of Art such accommodation on the upper floor in the galleries in Sauchiehall Street as they may require at a nominal rent of, say, 1*l.* per annum." This was finally approved of by the Parks and Galleries Trustees on January 7, 1892.

Although the accommodation thus offered would not be altogether satisfactory, yet, with alterations, it was hoped a fair School of Art would be obtained. The governors accepted the arrangement, recognising the desire of the Town Council to furnish accommodation suitable for the school, and knowing

* The higher scale shall apply to cases relating to lines of frontage, laying out of streets, open spaces about buildings, height of buildings, conversion of buildings into public buildings, and low-lying lands.

† The lower scale shall apply to all other cases.

that the relief from rent would be of great assistance to its finances.

Matters have thus remained from 1892 to the present time. They have now, however, assumed a new complexion.

The Bellahouston Trustees have, in reply to an appeal from the governors of the school, granted a bequest of 10,000*l.*, in the form of a free site costing 6,000*l.* and 4,000*l.* in cash, on condition that 6,000*l.* be raised otherwise.

The governors of the school have ascertained that a plain building giving accommodation equal to the present, and having nothing in its composition beyond the barest elements of utility, would cost not less than 15,000*l.*, exclusive of site.

The governors would appeal to the Town Council to make the School of Art such a grant as would secure the 10,000*l.*, which the Bellahouston Trustees have offered.

The governors lay these matters before the Town Council in the assured belief that favourable consideration will be given to their appeal, not only because of the special arrangement about premises mentioned above, but also because of the usefulness of the school itself. The raising of 11,000*l.* imposes a serious task upon the governors, and their only hope of accomplishing it is by the Town Council recognising, on the one hand, the benefits they will derive from the present premises being vacated, and on the other, the advantage of obtaining accommodation specially adapted to the needs of the school.

THE WAVERLEY HOTEL COMPETITION.

A LETTER has been addressed to the directors of the North British Railway, by Dr. Rowand Anderson, architect, with reference to the construction of the proposed hotel and offices at the Waverley Station. He says that the circumstances connected with the competition and the decision of the directors had been so extraordinary that he thought an explanation was due alike to the competitors, the architectural profession and the public. Apart from the competitor whose designs had been accepted, five architects of established reputation were invited to compete, and he was justified in saying that they all devoted much labour and expense to the preparation of their plans. It was freely stated to himself and others that they might save themselves the trouble of competing, as the result was a foregone conclusion. It was now abundantly evident that the designs had not been carefully considered. By whatever process the decision of the directors was arrived at, it certainly was not reached by the only proper course of considering each set of plans in detail and comparing them with each other. The directors could have entrusted the work of designing the building to any person they pleased, without going through the solemn farce of inviting designs. Having invited competition, they ought surely to have allowed a decent and sufficient interval for adequate consideration of the designs to elapse before announcing their decision, instead of adding insult and a public slight to the injury inflicted on the competitors, whose labour, thought and outlay had been wasted.

ARTS AND CRAFTS.

A LECTURE was given in the Glasgow Corporation Art Gallery by Mr. F. H. Newbery, head-master of the school of art. There was a crowded attendance, and the chair was occupied by Baillie Burt. The lecturer, who stated that the art and the workshop about which he intended to speak were those of Scotland past and present, gave as the argument of his lecture that handicraft, that is, work done by the human hand, was neither dead nor dying, but living and progressing; that if to facilitate wholesale production beyond bare necessities it had become an object that all labour that could be done by the machine should be done by the machine, yet this state of matters could never affect the question of the standard of artistic value of handicraft, for to produce that the machine was powerless; and lastly, that the present demand for technical education was largely a question affecting less the craftsmen working in a tradition of art handiwork than the workman waiting upon the machine. After defining terms and giving illustrations of what he meant by tradition, the lecturer took the art instincts of the Japanese, about which so much was heard and said, and compared them with those possessed by the Scottish nation when the village industries were thriving, and stated that the productions of the workmen here during that period would not find, as they do, choice places in æsthetic drawing-rooms unless there was something more than antiquity to recommend them. The beauty of these pieces of furniture, weaving, ironwork, &c., lay in their art and in their workmanship; that the presence of these qualities existed by the vital fact that they were made in workshops by art craftsmen; that the workshop was the centre of all art work;

and until this state of matters existed again no real progress could be made. No apology for the workshop was possible. Dealing next with traditional crafts which still exist among us, the lecturer dwelt upon the present state of handicraft education, ridiculing the rules laid down by the State as to trade teaching, and described very fully the method of State instruction pursued in France, which nation possessed a very complete system of technical education under State control, and produced workmen among the best in Europe. He stated that although this was the case, yet no country was in advance of Great Britain either in the standard of the work produced or in the class of artist designers who produced it, and finished by giving the outline of a scheme of education which might be adopted and fitted to our present system.

EDINBURGH ARCHITECTURAL ASSOCIATION.

AT the meeting of the Edinburgh Architectural Association, Mr. W. W. Robertson presiding, after the transaction of some formal business, Mr. A. Hunter Crawford read a paper on "The Suburban House." We were leaving behind us, said the lecturer, the idea that the portico of a Greek temple might be adapted to the porch of a suburban house, and we even thought now that the perfect propriety and respectability of Newington might be improved upon. The typical plan of the builder was inconvenient, unsatisfactory and commonplace. It was awkward without quaintness, and externally lacking in character. A well-designed house was homelike from the outside, convenient in its arrangements and interesting in its features. A good plan greatly depended on the size and arrangement of the hall and staircase, on the pantry and its relation to the dining-room, kitchen and entrance, and on the limited space wasted in passages. The lecturer illustrated by limelight views good and bad types of plans, and then proceeded to contrast stone and brick houses, advocating a freer use of brighter and warmer materials. Characteristic work by Messrs. R. Norman Shaw, R.A., George Sherrin, Ernest George & Peto, C. F. A. Voysey, Ernest Newton, E. J. May and other able architects was shown on the screen. The lecturer then referred to varied treatments of staircases, bedrooms and ingle-nooks, and closed his paper by expressing the wish that greater attention be given to the design of our houses, more particularly the smaller ones, and that Edinburgh might not only be noted for her beautiful situation, but also for her charming suburbs.

GLASGOW ARCHITECTURAL ASSOCIATION.

THE annual business meeting was held in the rooms, 114 West Campbell Street, the president, Mr. A. N. Paterson, in the chair. The seventeenth annual report, which was read by Mr. W. R. Watson, secretary, narrated the work of the Association during the past session. Memorials, it stated, had been addressed by the Association to the Town Council relative to the proposed removal of the Tron steeple, and to Her Majesty's Office of Works with reference to the repairs in progress at the cathedral. The most noteworthy event of the session had been the successful arrangement of a scheme of co-operation with the Glasgow Institute of Architects for the acquirement of premises to be jointly occupied by the two Societies. Owing to the difficulty of finding suitable accommodation the arrangement was deferred in the meantime. The Association Travelling Studentship, of the value of ten guineas, had been awarded after a close competition to Mr. George Gunn, member. Mr. Fraser, hon. treasurer, submitted the financial statement, after which the report was approved of. The following office-bearers were elected for the ensuing session:—Hon. president, Mr. Malcolm Stark, jun.; president, Mr. Alex. N. Paterson; vice-president, Mr. Wm. Tait Conner; secretary, Mr. Walter R. Watson; assistant secretary, Mr. Hugh Dale; treasurer, Mr. George Hill; librarian, Mr. Alex. McGibbon; general committee, Messrs. Wm. J. Anderson, George Copland, Wm. Fraser and Robert J. Gildard.

LIVERPOOL ARCHITECTURAL SOCIETY.

AT the meeting of this Society on Monday evening, in the Law Library, Union Court, Mr. Henry Hartley presided. He referred to the death of Mr. Charles Aldrich, F.R.I.B.A., saying that he was one of the oldest, most active and most esteemed members of their Society. Mr. T. Cook, in moving a vote of condolence with the family of Mr. Aldrich, said that his deceased friend was one who was highly thought of by the whole of the profession. Mr. Matear seconded the vote, which was carried. A paper by Mr. Percy S. Worthington, of Manchester, entitled "Churches of the Twelfth and Thirteenth Centuries in Burgundy," was afterwards read.

YORK ARCHITECTURAL SOCIETY.

AT the meeting of this Society Mr. John Lane delivered a lecture which was entitled "The City of Brussels." Mr. A. Pollard, past president, presided. In his lecture Mr. Lane described the places of interest in Brussels, considered both from the visitor's and the architect's point of view, and particularly mentioned the cathedral and chief churches, and the celebrated Palace of Justice and the boulevards. He also spoke of the laying-out of the existing city, and the improvements that had taken place in the buildings during the present century. The lecturer gave a short account of the history of Belgium, and of the wonderful progress that had been made during the reigns of Leopold I. and Leopold II., the present king. The lecture also included a description of Belgian peasant life, and treated of several places of interest in Belgium.

WOOD-PULP MOSAICS.

GERMAN has lately invented a process for manufacturing floor mosaics from wood-pulp, of which Const. Stern, of Bamberg, gives the following description:—Several particles of wood, such as saw-dust, fine shavings, &c., are soaked in a mixture of shellac and alcohol, so that the pores of the wood are penetrated and thoroughly dried. A cement, consisting of fresh cheese whey and slacked lime, is then prepared. This cement is thinned with water, and then mixed thoroughly with the already dry wood particles in such a way that the consistency of the mass is uniform. Particular care is taken to render the cement as thin as possible, so that it will distribute itself easily and uniformly, and enclose each particle of wood as perfectly as the shellac solution. The mixture thus produced is allowed to dry until it is only moist, not thoroughly dry as before, for in the latter case the curd would lose its cohesive power. The moist pulp is then put into heated mosaic moulds of the desired shape and size, and in these forms placed under the press. As a result of the heat the shellac softens, regaining its adhesive powers, and the curd cement hardens rapidly, so that both of the substances, the shellac as well as the cement, unite under the pressure so perfectly with the wood particles that the wood mass resulting may within a few minutes be taken out of the moulds without losing the form received. After the cooling process and complete hardening these mosaics, it is claimed, are far less susceptible to any change of temperature or moisture than any natural wood. It is necessary that the use of every other ingredient, especially if of an oily or fatty character, should be avoided in this character, as otherwise the close union of the shellac with the curd cement would be retarded or even prevented. Wood-pulp for the manufacture of multi-coloured mosaic is prepared in the following manner:—The particles of different varieties of wood are put through the process separately, so that the natural colour of the wood itself is brought into prominence. Dyes dissolved in alcohol are mixed with the shellac solution before the wood particles are coated. The wood particles are first coloured with dyes dissolved in water, and allowed to dry well before coating with the shellac solution. For simple floors it suffices to manufacture mosaics of different colours, changing them at pleasure, so as to form a variety of patterns. The manufacture of pattern or fancy wood mosaics is proceeded with as follows:—Pattern moulds of the required design divided into fields and figures are fitted into the plain mould; each section of the design is filled with the wood-pulp, dyed as before described, and the pattern mould removed, after which the whole, thus freely outlined, is subjected to heat and air pressure as before mentioned, the result being perfect varicoloured, fancy mosaic. This wood mosaic, in spite of its hardness and resisting qualities, still retains all the essential properties of wood, being adapted for use as floor covers in living-rooms and similar purposes.

PERPENDICULAR WINDOWS.

WHEN a Perpendicular window is of five lights, which is frequently the case in larger windows, the central light is a continuous panel from top to bottom, and from the mullions of this the sub-arches spring on either side, as in the clerestory of York and in Henry VII.'s Chapel. This arrangement does not occur in any other style. In debased Perpendicular work the window arch often becomes round, or the point is scarcely perceptible. The cusps in the tracery of Perpendicular windows are often formed in rather a different manner from those used in the earlier styles; they seem to grow more naturally out of the mullions, and are not so much like insertions; while in some examples of the Early English style they actually are worked on separate pieces and let in a groove in the mullion. This would be impossible with the Perpendicular cusps. The points of the cusps are sometimes ornamented with roses or foliage, as in the west front of Winchester

Cathedral and in a few of the original windows at New College, Oxford. In Perpendicular screens and other woodwork this sort of floriated cusp is very common. Not only the transoms, as already mentioned, but the sills also of windows of this style are often battlemented, as in the west window of Merton College Chapel, Oxford. This is one of the instances of the abuse of the battlement by using it too profusely as an ornament in this style. The Tudor flower ornament is almost equally abused in the later examples of this style; it is used on the transoms of windows, and instances may probably be found of its use on the sills also.

GENERAL.

Professor W. C. Unwin will deliver the "James Forrest" lecture this year, at the Institution of Civil Engineers, on "The Development of the Experimental Study of Heat Motors."

An Exhibition of paintings by eleven Scottish artists—mostly of the Glasgow school—is now open in Schneider's Gallery in Frankfurt.

Mr. Silvanus Trevail, architect, and Mayor of Truro, has been elected representative of that city in the County Council by a majority of 328. Mr. Trevail has been member for Truro during six years.

The late Admiral Beechey, who died at Southsea, possessed more than the average amateur's skill as a painter of sea-scapes. Many of his pictures are at Osborne. He was a son of Sir W. Beechey, R.A., the portraitist.

The Kirkwall Town Council were informed at their last meeting that heating or other pipes had been erected on the north side of the roof of St. Magnus Cathedral without the consent of the municipal authorities. The pipes were described as monstrosities, and it was unanimously agreed to order them to be taken down, and notice was to be given that if this were not done immediately, and the building restored to the same state it was in before operations were commenced, the work would be done by the Town Council at the expense of the contractor or the kirk session of St. Magnus.

The New Society called "Sunday Clubland" will be inaugurated at the Institute of Painters in Water-Colours on the 24th inst., the galleries having been secured for a succession of Sunday evenings during the summer and winter seasons.

M. Peynot's Design has been adopted for the memorial of the late President Carnot which is to be erected in Fontainebleau.

Mr. Caw has been appointed curator of the National Portrait Gallery, Edinburgh, an office which was held by the late Mr. J. M. Gray.

The Governors of the Llanelly Intermediate and Technical Schools have decided to advertise for plans and designs for schools to be erected on the site at Marble Hall, at a cost not exceeding 5,000*l*.

The Twelfth Annual Exhibition of Pictures painted by the Glasgow Society of Lady Artists has been opened.

Mr. J. Medland Taylor, of Manchester, last year prepared plans for the rearrangement and improvement of the great Renaissance church of St. Philip, Salford. The work is now about to be begun, and will include, as funds permit, interior decoration in mosaic, fresco or painting.

Mr. James Paton, curator of the Glasgow Corporation Art Galleries, has delivered a lecture on "The Great Venetian Painters" in the Museum Hall.

Mr. E. M. Leman, at the meeting of the Surveyors' Institution on Monday, the 18th inst., will read a paper on "Agricultural Credit Banks."

Colonel Edis, F.S.A., read a paper on "Internal Arrangement and Decorative Treatment of Town Houses" at the last meeting of the Architectural Section of the Glasgow Philosophical Society.

Mr. A. E. Campbell has resigned the post of borough surveyor at Stratford-on-Avon, having been appointed surveyor for the city of Canterbury.

The late Mr. E. G. Paley's estate has been valued at 71,934*l*., which will be divided among his family.

The Works Committee of the London School Board have recommended that an honorarium of 500*l*. be given to Mr. Bailey, the architect, for extra work.

The Death is announced of Mr. Waller Hugh Paton, R.S.A., at his residence in Edinburgh on Friday, after a severe illness, lasting about a fortnight.

The Water-Colour Society of Ireland have just opened their fortieth exhibition of pictures in the Leinster Lecture Hall, Dublin.

Mr. Batsford will shortly publish an important work on "Modern Opera Houses and Theatres," by Mr. E. O. Sachs and Mr. E. A. Woodrow, architects. It will contain about 220 plates, and will represent foreign and English practice.

The Architect.

THE WEEK.

THE party known as Progressives in the London County Council have only an insignificant majority, but apparently it will be employed to uphold and extend the abuses which have brought the Council into disrepute. There is no doubt that the reaction which produced such a remarkable effect at the last election was caused by the conduct of the works committee. If any respect for the electorate was found among the majority the arrangements of the works department would be forthwith changed. On Tuesday an opportunity was offered and rejected. It was proposed to erect a Fire Brigade station at Fulham. The original estimate was 10,500*l.*, but at the architect's desire the amount was increased to 11,400*l.* The change was evidence that the estimates are not always exact, and it is therefore absurd to expect that contractors should not hesitate in accepting them as guides. In fact the works committee sometimes decline to be bound by them. Mr. WESTACOTT moved that tenders should be sought through advertisements. By a majority of six that course was rejected. As long as a majority, however small, can be secured the people of London must be content to pay heavily while amateur builders and their hangers-on amuse themselves by erecting buildings. There would be an outcry if toy bricks were ordered to be supplied to the children in the London Board schools, but the amateurs of the County Council can have any materials that are desired, as well as operatives of every class to make sport, while those who pay have not the privilege of looking on.

It would be interesting to know how much is paid ostensibly by the London County Council, but in reality by the taxpayers, in imprudent actions which are decided against the Council in police and other courts. Everybody is gratified when foolish litigants are made to suffer, but when the Council are unsuccessful it is the people who have no share in the excitement who have to pay. The summoning under the Building Act of late years is becoming a scandal. The latest case was one in which it was sought to mulct Mr. GROVER, the builder, for making openings in a party-wall at the corner of Harewood Place and Oxford Street. That would be a serious offence, but as it happened there was no party-wall to break into. The site in question was formerly occupied with stables, which were taken down. A building six storeys high was erected, and it was sought to be made out that one of the high walls which superseded a low party-wall continued to be a party-wall, although no part of it stood on land belonging to another proprietor. The magistrate, after examining the building, said the wall was an external wall, and there was nothing in the Building Act or in any judge's decision which would make it a party-wall. He awarded 10*l.* 10*s.* costs against the London County Council, which was satisfactory to Mr. GROVER, but which sum he, like other inhabitants of London, will have to bear a share in repaying.

ABOUT a year ago negotiations took place between the Glasgow architects, surveyors, and representatives of the building trades, when eventually a system of measurement for builders' work was agreed upon. The adoption of the system could not, of course, be compulsory, but after the trouble which was taken in its preparation it should not be lightly ignored. One of the first departures from it has been in respect of some model dwellings which the Corporation are about to erect in King Street, Calton. The quantities for the work have been taken out on a novel method. In Glasgow contracts are entered into with the various trades. The brickbuilders were the first to take notice of the variation from the approved system. They at once applied to the city engineer, by whom the plans were prepared, inquiring whether his consent or permission for it had been obtained. Mr. McDONALD, in reply, said that attention was called in the schedules to the mode of measurement; that the Improvement Trustees in the present case have

directed very earnest attention to the best means for providing the most economical shelter for the poor, and the measurer framed his schedule in such a way as to attain the result at which the Improvement Trustees aim. The brickbuilders say that while they would be perfectly willing to tender on a schedule framed in conformity with the Glasgow Mode of Measurement, 1894, as agreed to by the associated trades in conjunction with the Institutes of Measurers and Architects, they most respectfully decline to tender on the schedule as framed. The blank schedules were accordingly returned.

THE manner in which mosaics are now made in Venice for decorative purposes is quite different from the elaborate system used by the ancients, which consisted in fixing the tesserae one by one on the cement previously applied on the wall. The modern method of the Venetian school consists in executing the mosaic in the workshop, by having the tesserae fixed with common paste on the section of the cartoon assigned to each workman. When all the parts of the mosaic are complete they are put together on the floor or on a special wooden frame. The mosaic, which is then a perfect representation of the original cartoon, is again divided into sections on the reverse side, marked with a progressive number, and carefully packed to be sent off to the place for which it is intended. The surface of the wall where the mosaic is to be fixed is then covered with cement, into which the sections of the mosaic are uniformly pressed, according to their numbers and the key-plan supplied to the fixers. When the cement has hardened, the paper on which the tesserae have been pasted is gently taken off, and the faithful copy of the original cartoon is again exhibited on the right side.

THE Town Hall of Aberdeen is not without shortcomings as an example of Gothic, but like KEMP's Monument in Edinburgh it is impressive and is well adapted to a granite city. In Aberdeen as elsewhere municipal business has to obey the law of evolution, and the homogeneous must become the heterogeneous. The building is therefore less convenient than formerly, and must be altered. We are glad to see the Council have not decided to carry out the necessary alterations by the municipal staff. A competition will be arranged in which all the local architects can take part. There will be an assessor to judge the designs who will not be an Aberdeen architect. The author of the design adopted will receive the usual percentage on the outlay, and prizes of 30*l.* and 20*l.* will be given to the authors of the designs awarded second and third places respectively.

ACCORDING to the original arrangements, the first of the biennial international exhibitions promoted by Venice, which is intended to be a show of strictly original and select works of art, is to be opened next month. It is likely, however, that there will be a little delay before the exhibition will be in a complete state. No artist will be allowed to exhibit more than two works, except in special cases to be decided by the managing committee. No work already exhibited in Italy will be admitted. The following prizes will be offered:—The city of Venice, 10,000 francs; the Italian Government, 5,000 francs; the Province, 5,000 francs; and the local Savings Bank, 5,000 francs. The two first prizes will only be awarded to works that have never been exhibited in any Italian or foreign exhibition. For the other two prizes works which are not new may compete, provided that they have never been exhibited at any public Italian shows. Works that have obtained prizes remain the property of their exhibitors. No one will be allowed to copy or reproduce in any way the works exhibited without a written permission from their owners.

IN Glasgow an effort has been made to enhance the interest in the exhibition now open in the Fine Arts Institute by allowing the visitors to vote upon the merits of the paintings. It has been determined by a majority of votes that Mr. A. W. ALLAN'S *The North Ford Uist* is the best landscape in the gallery. The *Lady of Shalott*, by Mr. WATERHOUSE, was assigned a similar position among the figure paintings. Both works were exhibited in London.

THE EDINBURGH COMPETITION.

IT was commonly supposed that the old way of conducting architectural competitions was at an end. The British sense of fair-play had discovered that the selection of designs by men who might not be competent to understand a plan was an abuse. The system adopted is not always satisfactory. Architects cannot claim to be infallible or impeccable when they act as assessors. The limitation of the office to a few men has had, too, the disadvantage of making competitors curry favour by demonstrating that they were inspired by the works of the assessor—a sort of flattery which the best-disposed architects are not always able to resist. But on the whole the change has not operated disadvantageously. After every competition grumbling is inevitable, but less of it was heard since the aid of assessors was enlisted. Moreover, it never arises, as was the case formerly, from a belief that corruption prevailed. If the assessor is to be set aside, it would be more equitable to gamble for the first prize than to return to the old incompetent tribunals.

The case which has just occurred at Edinburgh is a sign that the evil which has broken many a heart is not extirpated. Like the prevailing epidemic, it takes a rest and then is as vigorous as of yore. It also leaves a legacy which is irritating. The work which was the subject of the competition, although only a hotel and railway offices, was from its position one of those blocks which architects covet. All visitors to Edinburgh are aware that the buildings above the Waverley Station, which are to be displaced, are an eyesore, because, from their surroundings, they provoke a contrast which houses so mean cannot sustain. The proposed hotel which the North British Railway Co. have been shamed into undertaking will be one of the most prominent objects in the city. If successful, it will bring more fame to its designer than a more important work on a less favourable site. It is no wonder, therefore, that the six architects who were selected as competitors were envied by their brethren, and that those who failed in the contest are not so resigned as architectural philosophy dictates in such cases.

Was it through a perfervid eagerness to begin the struggle for so fascinating a prize, or was it from faith in Scottish honour that the six competitors were indifferent to the important question who was to decide between them, and by what process was the selection to be made? Dr. ROWAND ANDERSON expresses a truism when he says, "In dealing with designs for a work of such magnitude, involving the consideration of the grouping and arrangement of hundreds of apartments, the directors ought, in ordinary course, to have had expert assistance and advice alike, as to the more purely architectural quality of the designs and their practical adaptability to the purposes to which the buildings are intended to be put." His words are applicable to the majority of competitions. Dr. ROWAND ANDERSON must, however, have forgotten when he penned them that judging everything on earth and beyond the earth is the daily occupation of all Scotsmen. The country abounds in tribunals which are unconnected with the Court of Session. Small farmers and village tradesmen have no misgiving in determining questions that would keep the episcopal wisdom of England engaged for months or years. In mundane questions there is, if possible, less hesitation. The exercise may have its drawbacks, and they have been often pointed out by Scotsmen, but it has helped to make Scotland great. If railway directors conclude it is not their duty to cast the judging of plans on a temporary help any more than other important affairs, they cannot be expected to call in an assessor to gratify the authors of the plans. In the north deputies are less in favour than in the south, and it is wisest to let both countries adhere to the rules which have guided them. If the advantage of appointing an assessor were demonstrated to the directors of the North British Railway Company, they would perhaps have made a different sort of arrangement. But as the competitors were silent on that subject it is hardly fair to treat the directors as if they acted unfairly. They never promised to call in an assessor. "The letter of instructions," says Dr. ANDERSON, "stated that the directors should be the sole judges of the designs, but did not suggest that the directors were not to adopt the only possible methods of forming a judgment." In a case of so much importance why did not one or other of the competitors endeavour to

obtain a precise declaration on the subject? Architects are supposed to be familiar with the forms of business, and clients would not be gratified if they discovered that MACBETH'S words, "Nothing is but what is not," were applied as a principle in the interpretation of documents relating to contracts. Because the directors were silent on the subject of an assessor, by what law of logic should it be concluded that they had decided on his appointment? Why should the competitors' assumption be accepted as if it were a resolution duly entered on the minutes of the company?

We grant that the work undertaken by the directors was beyond the capacities of any small body of laymen in Scotland or England. Dr. ANDERSON says that he himself and a dozen of assistants were entirely occupied with the plans during eight weeks, and we may assume that the remaining competitors expended as much time, labour and money on theirs. The block treated contained a large hotel, offices and shops. The subject to be adjudged upon was therefore more complicated than any of the engineering schemes for operating on the Princes Street Gardens. But on that account the architects, as they were able to anticipate the character of their arrangements and were aware of the complexity of the problem, which the directors were not, should have had the foresight to insist, at least, on an investigation of their plans by some competent expert.

We may assume that the directors did not treat the plans as if they were competition designs for a poster to represent the scenery along their railway. There was time for a sort of examination. The drawings, we suppose, were sent in not later than February 11, and for all we know to the contrary, railway officials, a hotel manager or two, and some of the engineering staff may have been occupied with them during the two following days. A report dealing with the designs according to the company's requirement could also be prepared. In that way the directors would be able to arrive at a decision after a day's consideration of the report and drawings. So much expedition might not be seemly in dealing with architectural designs, but we suppose it was in keeping with the practice of the company.

Whether the best or the worst design was adopted we are unable to affirm, as we have not seen the drawings. As a rule the architectural work in connection with railways is only satisfactory in the eyes of the engineers and managers. Their principles are known to the initiated alone. But it is a pity that so exceptional a competition was not destined to have a more satisfactory result. If, as Dr. ANDERSON suggests, the result was a foregone conclusion from the first, no words can be too strong to condemn the conduct of the directors. There are, unfortunately, precedents for that sort of injustice, but as there was no compulsion on the directors to obtain designs by competition we cannot see what was to be gained for the shareholders by involving five architects in useless expenditure, anxiety and regrets. The statement it appears was freely made to some of the competitors before their operations were commenced, and their indifference to the method to be employed in judging becomes therefore more remarkable.

In all such cases of competition it should be remembered that there is no Court of Appeal for architects. What is called public opinion, with all its susceptibility, is not to be moved by any wrong inflicted on them. On that account there cannot be too much security sought in all arrangements relating to practice. The North British directors, like other bodies, are unable to realise how much has to be gone through in order to produce plans of a building. It is supposed they are not so difficult as plans of a line, because the latter represent work that is generally far more costly. When they find that designs for a work like the hotel and offices at the Waverley Station will be prepared by numerous architects without any stipulation that the examination and selection are not to be performed in secret, they are hardly to be blamed if they conclude that designing is easy, and the percentage paid for it is exorbitant.

M. Paul Lenfant, the well-known Paris architect, has died suddenly. He was a pupil of Constant Dufeu, and, with Davioud, constructed the Châtelet and Lyrique theatres.

WERNER VON SIEMENS.*

THE second volume of the Technical Papers by the late WERNER VON SIEMENS will probably be considered to have a more practical character than the companion volume, which we noticed when it appeared. Every page which the author produced related to practice, for, as he once explained, his imagination was controlled by reality. As he said of himself, "I have not been accustomed to give imaginary pictures without an actual serious background." The contents of the second volume on the whole have a nearer relation to the workaday world, for most of the pages relate to those applications of electric power which gained fame, wealth and influence for the author's firm. We can trace the history of his processes from March 1842, when Second-Lieutenant WERNER SIEMENS was granted a patent for dissolving gold by means of the galvanic current for gilding, until August 1890, when one was obtained for "Improvements in the apparatus for the measurement and summation of the energy passing through a conductor in continuous or alternating currents." We have in the volume exact descriptions of the scientific novelties produced by one of the most fertile inventors of the century. They are gainful for all who have an interest in the utilisations of electricity, and form a record which will always be invaluable for students of the history of the science. An abundance of diagrams is an auxiliary in the comprehension of the specifications. The apparatus for electric telegraphs, electric railways, electric lighting, electric writing and printing, electro-dynamic machinery, electric steering, electric hammering, &c., all owe much to WERNER VON SIEMENS. In one place we read of electricity as an aid against danger by fire, or as an aid against fire-damp in mines; in another of an electric voting telegraph, and elsewhere we not only have an account of an electric plough, but suggestions about "the possibility of producing food stuffs by means of electricity." The SIEMENS helped to realise ARIEL's scheme of putting a girdle round about the earth, but that achievement seemed to them to be only a modest instalment of what could be accomplished by means of electricity.

Men like the SIEMENS and their partner, Herr HALSKE, were novel phenomena in a country like Prussia, which half a century ago was not remarkable for its practical engineering. Apparently facilities were not given to them to conduct the operations which were to enrich the kingdom. There is a passage in the volume before us which suggests that circumlocution was not confined to England, and, strange to say, the principal agents who made the system embarrassing for the SIEMENS and men like them were architects. WERNER VON SIEMENS says:—

With us there is no place in the State organisation for the civil engineer, or any actual engineer; with us the architect is the technical organ of the State administration, the only material considered as qualified out of which the State forms its technical dignitaries, advisers and officials. With us a man must have studied architecture, not only, as in other countries, to build palaces and mansions, but streets, bridges and canals, as well as railways and telegraphs. Not even the laying out of our factories is permitted us without the directive action and control of the architect, to whose arrangements and decisions we must everywhere submit. That this multiplicity of study must lead to superficial knowledge, and can neither produce capable architects nor engineers, is quite comprehensible.

It may have been owing to prejudice against architects that so little is found in the volume relating to building. He has to deal with electric lighting, but apparently he was indifferent about the effect on the rooms or halls in which it was introduced. He was quite prepared to have the geometric streets of Berlin spoiled so long as lines of electric railways traversed them. In fact, the only part of the volume in which he expresses disappointment is where that subject is treated, as when he says:—

After the discovery of the dynamo-electric principle and the possibility thereby given to produce sufficiently strong currents cheaply, I already dreamed of a net of elevated electric railway lines over the streets of Berlin, whose low-water level unfortunately admitted of no underground railway system. But a long line of technical advance had first to be traversed, and a great deal more water will flow through the Spree before my dream can be carried out, even to a small degree.

Some excuse must be made for SIEMENS's indifference to architecture. In Berlin he could find reproductions of ancient forms as mechanical as any which might be turned

out by a machine set in motion by electricity. To a man of his temperament, who in his mind's eye could see a transformed world, an art which seemed to show a defiance of progress could only be considered as one of the survivals which were not worth respect. For a belief in progress inspires all the addresses which were delivered by WERNER VON SIEMENS. In a similar spirit to NEWTON, when he said he was like one standing on the sea-shore while the ocean of truth lay beyond untried, the electrician described himself as a mere dweller in the porch of science. He saw so many benefits arising from what was already made known by men of science, and turned to account by engineers, that his vision of the future was not dimmed by all the pessimism which his countrymen could create. Although the SIEMENS factories were colossal, he could not, however, suppose that the destiny of the world would never be attained until it had become one factory of innumerable workers, with a few directors. The great objection which many raise against the system is met by WERNER VON SIEMENS in the following way:—

For the further, and apparently most important, complaint of the opponents of our present social development—the assertion that through it the great majority of mankind was doomed to the performance of work in great factories, and that by the progressive division of labour there remains no space for free labour of the individual—also for this the natural progress of the development of the age of natural science has its own remedy. The necessity of large factories for the cheap production of articles of consumption is principally caused by the as yet small development of mechanical engineering. Hitherto large machines have supplied mechanical work much more cheaply than small, and the setting up of the latter in the dwellings of workmen is connected, moreover, with great difficulties. Engineering will, however, infallibly succeed in overcoming this obstacle to the return to competitive hand-labour, viz. by the introduction of cheap mechanical power, that basis of all industry, into small workshops and the dwellings of artisans. A number of great factories, in the hands of rich capitalists in which "slaves of work" drag out their miserable existence, is not, therefore, the goal of the development of the age of natural science, but a return to individual labour, or where the nature of things demands it, the carrying on of common workshops by unions of workmen, who will receive a sound basis only through the general extension of knowledge and civilisation, and through the possibility of obtaining cheaper capital.

NAPOLEON considered that after military science had performed its best or worst in destroying men, there would be a return to the warfare of the Homeric times. It is therefore not improbable that the craftsman of the future will possess a machine of sufficient power to aid instead of superseding him. Nor will he consider he is acting unworthily by utilising it as a means to extend his own power. Let us imagine BENVENUTO CELLINI before some of the delicate cutting and drilling machines for dentistry which are imported from America. Can we suppose that he would not perceive the value of an instrument that was able, when guided by him, not only to save time, but to help him to realise designs more effectively? A machine of the kind is no more than one or several tools of a special kind, and as long as hammers, punches and chisels are allowed, a machine which combines them should not be rejected. But before producers on a small scale can again flourish there must be a vast change in the ethics of trade. Germany especially will have to again reform itself. WERNER VON SIEMENS was a German of the highest class, but with all his affection for his countrymen he did not hesitate to point out a weakness of theirs which has become infectious, and is producing incalculable mischief. One passage deserves to be given as proof of the honesty and courage of the man:—

Whilst in England, France and even in America it is considered dishonourable, or at least unbecoming, to make use of foreign inventions without the consent of the inventor, even if his right to protection is doubtful or does not exist, in Germany this is not only considered proper, but in many cases even meritorious. As a characteristic example in this direction, I only need cite that in Prussia itself technical State officials do not hesitate to deliver to other manufacturers as a pattern for imitation new mechanical apparatus or arrangements which are perfected by manufacturers with difficulty and expense, or to bring them into competition and to assign the execution to the lowest tenderer. They are even often obliged to do so by their instructions. In a similar direction those manufacturers frequently openly recommend their manufacture to us on this ground, that they imitate on principle only the most approved and most novel constructions of recognised important firms, and therefore can supply cheaper than these, as they had to bear no expense of imitation and trial. In other countries this would be considered as dishonourable; here, even State officials do not hesitate to make the best use of such apparently advantageous offers. The natural consequence is, that this anomalous

morality by degrees permeates from above downwards through the whole life of trade and commerce, that the endeavour to furnish what is new and better in industry occurs more seldom, that competition for cheapness alone is predominant, and German manufacture is everywhere disposed as goods of slight value. The gratifying pride of the English manufacturers, whom no prospect of gain would induce to provide goods with his mark which were not first class and would do honour to his firm, is unfortunately only in a few cases to be discovered amongst us. . . . German honesty, of which we sing and speak much, has abroad only a bad sound, to Germany's immeasurable harm. This dislike everywhere abroad to Germans and German ways has recently considerably increased.

But if the "anomalous morality" has been injurious to Germany and other lands where electric machinery and apparatus are produced, how would it work with the electro-chemical food which was one of those dreams of SIEMENS which had a basis of reality? Long ago Sir JOHN HERSCHEL gave his approval to a scheme for making bread out of sawdust, by which famines were to be rendered impossible. But WERNER VON SIEMENS went infinitely further, for he considered that a substance of the organic nature of sawdust was unnecessary. His nitrogenous food will probably not require teeth for mastication, and will therefore be suited for a time which is fast approaching when teeth will be mere ornamental appendages. The proposition is one of the most daring in the book, and what chemist would say it was impracticable?

Hydrogen and oxygen—explosive gas—is an excellent fuel, but difficult to apply. But in place of water, common salt, or another fusible salt, it can be decomposed by the electric current, and we have besides in solid sodium, potassium, magnesium or calcium fuels in solid form, produced with the help of the electric current by natural forces which are already more useful. It is, therefore, no baseless imagination, but a supposition based on quite determined facts, that in this way fuel can be produced by the application of forces existing in nature. The question of the production of foods is a much more difficult one. These are also essentially fuels. We burn the substance of the food by means of different chemical actions which occur in our bodies, and thereby supply the heat our life requires. But there is a second condition to be complied with. We must produce or renew the nitrogen combinations of our body. It is, therefore, necessary that the food should contain nitrogen combinations. Nitrogen is a peculiar body, which only enters with difficulty into combination with other substances. It is, therefore, necessary in order to produce food stuffs to arrive at means of getting over the difficulty of combining nitrogen. In organic nature this takes place by means of the life process of plants. In inorganic nature we have only nitric acid and combinations of ammonia, the origin of which is somewhat obscure. Therefore, in fact, my opinion that it would be possible at some future day to produce artificial food, which must contain nitrogen, would be a dream if a direction, a way did not already exist which gave a prospect of attaining in future the realisation of this hypothesis. (Werner von Siemens then described his ozone apparatus which would produce commercial nitrogen combinations). It is merely a thing of ordinary scientific technical advance to arrive at the production of nitrogenous bodies by a combination of chemistry with electrical science. In the same way hydrogen is produced in the so-called active condition in the ozone apparatus. It is therefore possible to produce mechanically in the future products belonging to the series of ammonia combinations. Whether electric chemistry will indeed solve the problem of so combining the substances necessary for nourishment that the animal body can assimilate them and make use of them as food lies in the future. Anyway, my opinion is no dream, but an hypothesis resting on a strong scientific basis.

The extracts will suggest that WERNER VON SIEMENS, when he allowed himself opportunities to treat of subjects outside his laboratory, was fearless, sympathetic, far-seeing and versatile. It is, however, as an inventor he is greatest, and there can be no better testimony to him as such than the precise descriptions of his discoveries and inventions in the collection of technical papers with which scientific literature has been enriched.

GOTHIC ARCHITECTURE.

A LECTURE in the Glasgow School of Art on English Gothic architecture, with reference to cathedrals, has been delivered by Mr. W. J. Anderson, architect. The general principles of their design were explained and compared with those of other styles, their divergencies from the continental type and the characteristics of their various periods. The Early English period was divided into lancet and geometric, and the term curvilinear preferred to decorated, as these forms in the window tracery were in England, an almost unvarying mark of the date of the building. In French Gothic the constant aim of the designer was to produce overpowering effect of internal height, the vaulted roofs demanding for their support a great scaffolding of superimposed flying buttresses as at Beauvais and

Bourges, which externally destroyed all sense of repose, suggesting nothing so much as a "half-built ship on its shores." If this was to be defended and praised in the prevailing fashion as the only true Gothic and the logical outcome of the Gothic idea, we were forced to believe that the Gothic idea carried to its conclusion was opposed to sound constructive science and to æsthetic effect. But the English mind of the thirteenth century aimed at an impression of great internal length and moderate height of avenues, which served their chief purpose best, and at the same time had the happiest effect externally, enabling them to rear such a central tower as would be the glory of the whole fabric. The great length gave repose externally, and the bold transept projection aided materially to produce a picturesque effect from any point of view. The group of central and western towers generally designed for English cathedrals, and carried out at Carlisle, Lichfield, York and Lincoln, was the finest that could be imagined, and there was no possible vantage ground which would give a disappointing view of such buildings. The apsidal termination of the interior of the French churches was magnificent, but was almost compensated for by the splendid eastern window of the English at Carlisle and Lincoln, for example, and the good appearance of the square end externally. The greater number of the English cathedrals were shown by lantern views, externally and internally and in detail, and a short series of views of Scottish architecture followed. The lecturer contended that in the main Scottish Gothic architecture does not differ materially from English work, and was less influenced by French Gothic than had been popularly supposed. Scotland was strong in transitional work, which often took the form of the pointed arch with Norman mouldings and the French square abacus and capital, as if the form of the pointed arch had travelled northward more swiftly than the appropriate details of the Gothic style. This it was which gave it the resemblance to French Gothic, as at Jedburgh nave, and this, it was suggested, had misled critics. In the chief distinctive features of the French style—excessive height, absence of central tower, general use of the apsidal termination, the square arch order, the central buttresses and chapels and the rose windows—Scotland had no part with France and the marks of French influence were not nearly so apparent as of English.

THE STORY OF TEL-EL-AMARNA.

A LECTURE was delivered before the Royal Dublin Society on the 13th inst. by Mr. Laurence E. Steele, M.A., entitled "A Romance in Egyptian Exploration: the Story of Tel-el-Amarna." He said:—Some two or three years ago, when the name of Tel-el-Amarna began to appear in our newspapers and magazines, people were much puzzled as to the import of the reference. Some, under the impression that it was the name of a new king unearthed by the explorers, asked "Who is Tel-el-Amarna?" Others, less anxious to display their very pardonable ignorance, put the question more cautiously, and asked "What is Tel-el-Amarna?" And it is even recorded that when references to the now famous clay tablets of Tel-el-Amarna began to occur, a wholesale druggist received a large order from an old and respectable customer, who concluded that they were a new form of voice-lozenge. It is perhaps unnecessary to remind this audience that Tel-el-Amarna is the name of a modern Arab village which is near the site of an old Egyptian city founded by a certain King Khuenaten, and which lies about 160 miles south of Cairo, on the eastern bank of the Nile, where the explorers have brought to light an extraordinary series of relics of the past. Mr. Steele, with the assistance of a large number of photographs, explained the characteristics of the period to which the extraordinary discoveries made by Professor Flinders Petrie had been assigned, and continued:—In studying any one of the many wonderful discoveries in Egypt of recent date, the very first thing we must do is to get as clear a conception as possible of the time to which the archaeologist proposes to assign the discovery. The discoveries at Tel-el-Amarna have been identified as belonging to the period of the eighteenth dynasty, the first king of which line commenced to reign in 1587 B.C. Let us realise the remoteness of this date. We may remember that Mary Queen of Scots was executed in the year 1587 A.D., so King Ahmes was as remote from the birth of Christ on the one side as that event in English history is remote on the other. And, again, we see that this dynasty lasted from 1587 B.C. to 1328 B.C., a space of 260 years, and that it contained fourteen kings. We may remember that our eight Plantagenet kings reigned for 245 years, so in duration this powerful Egyptian dynasty exceeded in length the line of our brilliant Plantagenet sovereigns by just fifteen years. But where does this date find us in reference to the chronology of other nations? Let us examine this "time-measuring rod" on which the dates are marked off in accordance with a scheme of chronology which has been published only within the last few months,

and we shall find that King Ahmes commenced to reign 800 years before the last Olympiad, when, in the year 776 B.C. reliable Greek history begins. But this difference of 800 years dwindles into insignificance when we come to consider this eighteenth line of sovereigns in relation to the majestic sweep of centuries through which the august potestates of Egyptian dynasties stretch in imposing array. For King Ahmes, as he looked back upon the gorgeous history of the past, would have to carry his memory back to a period no less than 400 years more remote than we are now from the birth of Christ, if he wished to realise the period at which King Cheops, of the fourth dynasty, erected the great Pyramid of Ghizeh, about 4,000 years B.C., at which point reliable monumental history begins. The most interesting of the sovereigns of this eighteenth dynasty were Queen Hatasu, Thothmes III., the constructor of the Thames Embankment obelisk, who died on St. Valentine's Day, 1449 B.C., Amenhotep III., and his son Khuenaten, the founder and builder of the old city near Tel-el-Amarna. The mummy of a preceding sovereign, Thothmes II., was discovered in the great find of mummies in 1881 at Deir-el-Bahari, near Thebes, and presented a curious problem for the physician. It was noticed that the body bore traces of some form of cutaneous disorder. Of this there was no doubt, but for the truth of the following incident, he (the lecturer), was unable to vouch. The doctors could come to no conclusion as to the nature of the affection, until the suggestion was offered that a careful examination should be made of the upper part of the left arm for certain well-known marks, but without result. Careful search was also made amongst the records for any reference to an Egyptian functionary at all analogous to our medical officer of health, or for any trace in the Egyptian legal system of compulsory vaccination, but in vain. We are therefore driven to the sad and inevitable conclusion that the great king perished miserably a victim to a prevailing epidemic. Queen Hatasu was possessed of a strange fancy. She always chose to speak of and represent herself as a king and not as a queen. She was a woman of great force of character, and managed to keep her two brothers off the throne of Egypt as long as possible. In this picture, executed by her direction, you see her carrying her masculine proclivities so far as to assume the dress of a man, even going so far as to add a beard. The historical parallel is obvious. There is nothing new under the sun, not even the new woman, for here we have the new woman existing no less than 3,400 years ago. But Queen Hatasu was a woman of superb artistic perceptions, and to her is due the erection of the lovely rose-coloured obelisk, only 8 feet short of the height of Nelson's Pillar, which stands in the midst of the ruins of Karnak—her greatest architectural triumph being the temple at Deir-el-Bahari, which the officers of the Egyptian Exploration Fund are at this moment clearing. Having shown some other photographs illustrative of this period of the eighteenth dynasty, the lecturer proceeded to explain, with the aid of photographs from the relics discovered at Tel-el-Amarna, the particular direction in which King Khuenaten exhibited an independence and an originality unparalleled in the history of Egypt, and continued:—To the ordinary traveller Tel-el-Amarna, until within the last two or three years, was an uninteresting spot, for nearly everything above ground was swept away within thirty years of the death of its founder—a few low and ruinous walls alone marking the site of the great city. The same oblivion had fallen upon the memory of its founder, and except for some caricatures of the king, and stories which all conspired to blacken his character with charges of heresy and other infamy, little was really known of him until Professor Flinders Petrie undertook the thorough examination of the spot, which has resulted in the rehabilitation of the character of the king, and in placing him in a unique position amongst the monarchs of Egypt as the originator of a religion and an art unexampled in the history of the land; for to him and to the group of artists which his strange personality attracted to Tel-el-Amarna, belongs the credit of having introduced for the first time the idea of perspective into Egyptian drawing and painting. Having shown several examples of the art of the time of Khuenaten, particularly some interesting and realistic paintings of "animals in motion," the lecturer said:—Having learned something of the works of this most original man, it becomes a matter of supreme interest to see if we can summon up from the dead past some portraiture of King Khuenaten, which will enable us to realise his personal appearance. We have not secured his mummy, as is the case with so many of his immediate ancestors, whose bodies were found in the year 1881 in an unsuspected rock-cut chamber at Deir-el-Bahari, but we have something far more valuable and more natural than the expressionless face of a parched mummy to enable us to recall the features of Khuenaten. To this part of the story of Tel-el-Amarna belongs the most sensational discovery. The now famous tablets of Tel-el-Amarna have thrown a marvellous flood of light upon the family history of King Khuenaten. We know from them that Khuenaten's father,

Amenhotep III., married a Mesopotamian princess, and who, there is a strong presumption in concluding, was the mother of Khuenaten. Her name is well known. She was a certain Princess Thyi, and her name and portrait appear many a time upon the monuments. Now, Khuenaten was an ugly man—of that fact we can assure ourselves by a glance at the picture on the screen—and is strangely unlike the portraits and mummies which recall the features of his immediate ancestors. It could also be shown that he was fat and ungainly, and he possessed none of that slim grace which appears to have been a thing of beauty in the eyes of the later Egyptian. But we must be content with an examination of his face. We perceive that the characteristic feature of his profile which is noticeable in this and in every other known portrait of the man is his protruding and abnormally-developed chin. It becomes an interesting question in heredity to learn how he came by this chin, which his father and his grandfather most certainly did not possess. The explorations at Tel-el-Amarna have given the clue by supplying us with several portraits of the Princess Thyi, which have demonstrated beyond any shadow of doubt that this strange cast of feature was inherited from his Mesopotamian mother. Now this by no means implies that Khuenaten's mother was an ugly woman. He (the lecturer) would be sorry to state the fact, even if it were true; but the monuments prove the contrary, and this picture of the queen is by no means an unpleasing portrait. She has the same strongly-marked, commanding chin which is so accentuated in her son's features. This peculiar cast of feature appears to have been characteristic of the Mesopotamian, as will appear from this sculptured head of a man of Mesopotamia, in which the same racial characteristics are expressed with plebeian coarseness. But this is not all. What is far more valuable than the mummy of Khuenaten has been found—what is far more life-like, if the paradox be excused—namely, the king's death-mask. Having exhibited a photograph of the cast of the face and head of Khuenaten, taken from the dead king's features, and found by Professor Petrie amidst the ruins, and having shown by a comparison with the death-mask of Dean Swift, preserved in the Anatomical Museum in Trinity College, the naturalness of the death-mask made over 3,000 years ago, the lecturer concluded by remarking that here the story of Tel-el-Amarna may fitly close with this last illustration of the relics of a past age found on the site. Driven from his old home at Thebes, Khuenaten died, like Alexander the Great, at the age of thirty, and with him perished all that he had lived for and all that he had worked for. It was the fall of one of the great movements of human thought, carried out by a single idealist, who set himself against the traditions, the religion and the habits of his country.

ABERDEEN ARTISTS' SOCIETY.

THE annual meeting of the Aberdeen Artists' Society was held on the 13th inst.; the Marquis of Huntly, president, was chairman. The annual report stated that the last exhibition was the most successful ever held in Aberdeen from an artist's point of view. The value of pictures sold was 2,528*l.*, being an increase compared with last season of 1,003*l.* The receipts for admission, catalogues and commission on pictures amounted to 266*l.* 1*s.*, or 10*s.* 5*d.* less than at the exhibition last year. The expenses amounted to 554*l.*, being 9*l.* 0*s.* 10*d.* less than at the previous exhibition. The annual subscriptions from 463 members (240 ordinary and 223 honorary) amounted this year to 350*l.* 12*s.* 6*d.*, and last year the subscriptions from 459 members (260 ordinary and 199 honorary) amounted to 358*l.* This year there was a net gain on the exhibition account of 62*l.* 12*s.*, as compared with a gain of 62*l.* 1*s.* 1*d.* on that of last year. The net profit on the season amounted to 67*l.* 11*s.* 8*d.*, which, added to 134*l.* 1*s.* 4*d.* in bank, makes a total of 201*l.* 16*s.* 6*d.* at credit of capital account.

The Chairman said he thought the members had a right to congratulate themselves upon the position the Aberdeen Artists' Society had now assumed, and he thought they would agree with him that the report submitted was most gratifying. The curious thing to observe was that, although the last two exhibitions were held at different times of the year, they had had pecuniarily almost the same result. Some of the members thought that holding an exhibition in the winter months would not be so satisfactory as the spring months, but he was glad to say that the art-loving public of Aberdeen had attended and patronised the exhibition as freely in the winter as they did in the summer. At all events, if they wished, they could continue their work with confidence, and if they continued it on the present lines they would certainly not become bankrupt. He thought in every way they could say the exhibition was a great success. He did not think there was any exhibition they had had in Aberdeen that so thoroughly typified all the forms of art and styles of painting, and he thought so thoroughly appreciated by the people of Aberdeen and district. And he only

hoped that, now they had sailed so successfully, the Aberdeen Artists' Society would continue to flourish. He should like to say something about the future. Perhaps they would not be able to have so large an exhibition at an early date as the last one, but he thought the Council might consider whether they could not have a similar exhibition of some sort, including local objects of interest, in connection with the approaching opening of the Marischal College buildings in October. At the end of next October there would likely be a considerable flourish of trumpets at Marischal College and a very interesting ceremony, and it would not be out of place, he thought, to get together in the galleries an exhibition of Aberdeen art and objects of interest to Aberdonians, and perhaps the exhibition might be made one which the public would patronise, and would be deserving of the success that had attended other exhibitions. He threw out the suggestion, although he did not suppose it would be possible to get a large exhibition of loan pictures on that occasion; but he thought there was enough in this district to make up a very interesting exhibition. He had much pleasure in moving the adoption of the report.

EDINBURGH ARCHITECTURAL ASSOCIATION.

ON Saturday the members of the Edinburgh Architectural Association visited the village of Upper Liberton, and were conducted over Liberton House, the former residence of the Littles, the owners of the Barony, by Mr. G. Godfrey Cunningham, advocate, the present occupant. The attention of the party was directed, in the first place, to the ground plan of the house, consisting of two blocks of building at right angles to each other, with a circular turret or tower in the angle, these, together with another block or annexe, enclosing on three sides a small square courtyard, the fourth side of which was once shut in by a wall and gate of defensive character. The special interest attaching to Liberton House lay in the fact that it belonged to a transition period, when defensive architecture, even in the case of structures without any claim to rank as a castle or fortress, had not yet been wholly abandoned, and when the state of society made it necessary to retain safeguards against sudden attack. Though disfigured externally by an alteration in the height of the walls, which had been considerably raised, and in the pitch of the roof, which had been depressed, the outlines of the original elevation were still clearly traceable. Lastly, the "Nelson room," a reconstruction of recent date, was explained to be an attempt arising out of structural considerations to introduce the half-timbered work associated, at least in Scotland, more often with the exterior than with the interior of the edifices in which it occurs. At the close of the visit the president, Mr. W. W. Robertson, F.S.A.Scot., proposed a vote of thanks to Mr. Cunningham, which that gentleman duly acknowledged.

TESSERÆ.

The Window Heads of Heriot's Hospital, Edinburgh.

EXTERNALLY great character is given to this building by the four square tower-like masses that adorn the angles; and between these, in what may be called the curtains, the windows are disposed without much attention to regularity either in design or position, the ornaments of each window being different, though all belonging to a class which is almost peculiar to Scotland. Generally the windows are adorned with a pilaster on each side supporting a richly-ornamented entablature, but above that, instead of the usual straight-lined or curved pediment used by the Romans and copied from them by the Italians, the Scotch employed a rich complicated piece of blind tracery, if it may be so called. As used by them, the effect is not always pleasing, the design being frequently ungraceful and the ornaments grotesque; but it is very questionable whether in principle it is not a more legitimate mode of adorning a window-head than the one we so generally make use of. It admits, at all events, of the most infinite variety of detail. Some of those at Glasgow College or in Regent Murray's house in the Canongate were as elegant as any; but there is scarcely a Scotch house of the early part of the seventeenth century which has not specimens to contribute. The style of these ornaments is singularly characteristic of the age. They show that love for quips and quibbles which pervades the literature of the day, but they show also that desire for cheapness which rather than beauty was the aim of the builders. Every architect knows how difficult it is to design and how much more difficult it is to cut all the hollow and curved mouldings which characterise every shaft and every mullion in the pure Gothic style, and how much its beauty depends on their delicacy and variety. Here, however, it is merely a square sinking, such as might be cut out of deal with a saw; and though it does produce a considerable effect at small cost, and is consistent with all the mouldings and mullions

of the style, it will not bear examination even when enriched and embossed, as it sometimes is, in pilasters and other features. Like all the other details of the age they never reach the elegance of the Classical and are immeasurably inferior to those of the Gothic style which preceded it.

Appreciation of Art.

There is in fact no more distinctive and vital characteristic of true art than its universality. Really creative power is neither for this time nor for that class, but for all time and for all classes—for the present as for the future, and for the future as for the present. The poet, the painter, the sculptor, the musician, the architect appeal in their highest efforts to sympathies, aggregate as well as individual. From this inherent condition of universality in all great works of art emanate three especial bonds of union and affection—firstly, between genius and the world at large; secondly, between genius and all who, however devoid of it, may be endeavouring to achieve success in the same department of art, and thirdly, between genius and kindred spirits of all ages, who in pursuits of the most widely differing natures have reared their heads aloft above the average of mortality, and won admission to the noble brotherhood whose names have become landmarks in the history of civilisation. In the death of every great artist these bonds receive a sudden shock, which, however it may jar and strain, can never break them. There can be no higher tribute to the ascendancy of genius than this impotence of death itself to finally sever bonds of union between mind and mind, which it can only shatter, and it is the very measure of this impotence which affords the best scale for ascertaining the nature, force and amount of the loftiest order of human creative power.

Colour in Painting.

In his fourth discourse Reynolds appears to consider colour as a merely sensual element of art. It is certainly no more so in the common and gross meaning of the word than form or light and shade. All these may be equally used to render subjects that appeal to our lowest passions attractive, and for this end Correggio has availed himself more of light and shade than of colour. Errors of this kind arise from confounding the art with the subject, and it is one of the first things necessary that the student should keep these entirely distinct in his mind. If he hopes to benefit substantially by the study of art, he must learn to see that qualities have often no necessary connection whatever which are nevertheless inseparably united in particular styles, as, for instance, the grossness of form in Rubens with his manner of composition or with the hues of his flesh, or the *chiaroscuro* of Rembrandt, the simplicity and truth of his expression, with the deformity and meanness so often found among his groups. But colour has been considered sensual, according to another meaning of the word, as addressing itself to the eye only, and not to the mind. This, however, like the first objection, applies no more to colour exclusively than to any other quality of art. Beauty of form or truth of light and shadow address themselves as much to the eye and no more to the mind and colour unless they express a sentiment, and colour may appeal to the mind as powerfully as either, particularly in the expressions of gaiety, of sadness, or of solemnity. Sir Joshua seems also to rate colour too much as a merely ornamental quality; but every part of the art is ornamental, and if colour be more so in some schools than in others, it is only because it is truer in those schools to nature. We must not confound the materials the Venetian painters introduced into their pictures with the media of their art—the effects of their rich velvets, satins, brocades, &c., with those beauties of nature, her brightness, splendour and harmony of tone, which they first gave in perfection, and which might as well adorn the poorest and coarsest materials as the richest. It is not that Paul Veronese is gayer in colour than Raphael, but he is truer, and seems completely to have attained that which Raphael aimed at in nearly all his subjects, namely, the broad light of tranquil midday. The most solemn, the most mournful tones, and tones suited to the most sublime subjects, may be found in the works of Titian, of Tintoretto, and even of Paul Veronese, as well as colour the most magnificent; but the distinguishing excellence of the Venetian and of the Dutch and Flemish schools is that, whatever be the choice of colours—whether the tints be brilliant, rich, or negative—whether the effects be light or dark—the true tone of nature is spread over the whole. Till a finer tone be discovered, I can never think that Venetian or Dutch colour can do otherwise than exalt the highest subjects; and it seems, therefore, to me a most injurious error for painters to think of colour as a thing that may be either neglected as a minor excellence, or deliberately rejected as inconsistent with other qualities. Such may be a convenient mode of thinking, but it never was the way in which any really great painter ever thought or felt; and it is curious to see in the writings of Reynolds his natural love of colour breaking out in detached passages, and confuting his own theory of the incompatibility of the excellences of the Venetian

of Dutch with those of the Roman schools. He admits in one place that the colour of Titian might assimilate with the grandest subjects, and in another he says, "Jan Steen had a fine manly style of painting that might become even the design of Raphael."

Prehistoric Periods.

According to Dr. John Evans the Iron Age in Western Europe lasted until about the Christian era, and in Britain the Bronze Age may have extended from about 1400 or 1200 B.C. to 500 or 400 B.C., and the Neolithic period for about 2,000 or more years previously. But in this country it is not possible to fix precise limits for those (to us prehistoric) periods. In Neolithic times the only metal known was gold. Later on the prevalence of implements and weapons of bronze before those of iron in this country, as in other parts of Western Europe, is remarkable. Bronze or gun-metal is an alloy in the proportion of nine parts of copper and one of tin, and copper was the first metal which became of real importance to man. Tin also early attracted notice, probably on account of the great heaviness of its ores, and when metals were very scarce it would naturally sometimes happen that, in order to make up the necessary quantity some of tin would be added to copper, or *vice versa*. In this way Sir John Lubbock accounts for the early use of bronze. In these later prehistoric times we had dwellings like those of the Swiss lake population, as at Barton Mere, in Suffolk, and at Ulrome, in Holderness. We have also the pit dwellings, such as those of Standlake, west of Oxford, of which pits a model is preserved in the Ashmolean Museum, but many of the so-called pit dwellings are in reality excavations made for stone or gravel. The Deneholes and the Beehive pits or granaries on Portland are not without geological interest, although their precise age is uncertain. We have the Druidical remains of Avebury and those of Stonehenge, which are referred to the later part of the Bronze Age.

Greek Myths and Greek Art.

The interpretation of the motive and meaning of Greek art is essential not only to the understanding of the art itself, but also to the due appreciation of the Greek mind. What is commonly called mythology or the tradition of the myth, as recorded and interpreted in Greek literature, appears to ordinary minds but as darkness visible, an image distorted by the various media through which it is conveyed; but the traditions of the same myth in contemporary art, which we may call mythography, enables us to trace out far more clearly and readily the expression of popular faith before a rationalistic philosophy had refined away its essence. Without mythography, as it is conceived, we cannot understand mythology. The monuments of art which archæology has collected acquaint us with the mythography of many races, and thus through the comparison of visible objects made by the eye, enable us to compare that which is matter of thought, the religious idea conveyed in this sensuous form. If we pass from the Elgin to the Egyptian Room in the British Museum, we feel a contrast, a difference, not of forms merely, but of the thoughts suggested to us by those forms. To account for this difference we must not only compare the two races by whom these two styles were produced in regard to their original character and habits of thought, but recur to the primary sources of mythology itself. The earliest religious and philosophical teaching in Pagan races generally was conveyed in the figurative expression of art and poetry, not so much from choice as necessity, from the imperfect development of conventional language and writing. The process by which the myth was thus, as it were, self-engendered out of the natural wants and questionings of primeval man was probably common to Pagan races generally. Its subsequent development was affected very variously according to the mental qualities, climate and external circumstances of the different nations, and it is thus that the myth as represented in their art and literature becomes a standard by which we may measure their relative mental capacities and intellectual progress. The Greek myth, as it underwent the plastic influence of the poet and the artist, became a beautiful work of the imagination—a bond of sympathy between the Greek and all future civilised races. The myth of the Egyptians, Assyrians and other less favoured races, remained as it was from the first, the monstrous creation of a fancy unrefined by culture. It was the free and vigorous growth of art and poetry that emancipated the Greek myth from the thralldom of prescribed forms; it was the inborn sense of beauty and fitness in the Greek mind that in the construction of their mythic types rejected, with a few exceptions, those combinations which nothing but long association can make pleasing to the sight or the mind. As Greek poetry and art grew up independent of all such influence as checked the growth of the Egyptian mind, the myth lost a hieratic and assumed a popular form. When once permanently recorded in sculpture and written poetry, it unconsciously underwent modifications not suggested by religious feeling but imposed to meet the conditions of art. As we trace the history of the myth, these its modifications from external influences become more complicated. Poetry suggests

new varieties to the artist, art to the poet; mythography and mythology react on each other, the figurative language of both becomes more subtle and expresses fewer intellectual distinctions. As mirrors multiply light, so is the natural fertility of the Greek imagination quickened by these mutual reflections of its art and poetry. Types breed and increase, the love of novelty demands new combinations, and, as imagination becomes exhausted in the supply, these are sought for in the types of exotic deities introduced by commerce or conquest, or in the revival of archaic and forgotten myths. The tradition of the myth subjected generally to these modifying influences of art and poetry was further changed by transplantation into different localities. The isolation and unwillingness to centralise, which is the characteristic of the Greek communities, led to endless local varieties in the common myth—differences which are as peculiar dialects in the figurative language of ancient religious teaching. Again the exotic influences which must have been more or less in action from the first become very apparent after the conquest of Alexander in the fusion of Greek with foreign types of divinities, the result of the blending of races in the kingdoms formed by that monarch's successors. This led rapidly to the motley pantheism of the Roman empire. In the art of the Augustan age and subsequently we find many examples of these combinations in mythography, sometimes treated with exquisite skill, as in the blended types of Bacchus and Cupid—sometimes monstrous anomalies, as in the well-known Diana of Ephesus.

Pictorial Perspective.

There are two things to be looked for in books of perspective, but which are rarely seen in modern works. The first is:—Given the position of a point in space, required the position of that point on the picture. The second is this:—Given the proportions of the parts of a line in the picture, required the proportions of the parts of the original line, or *vice versa*. Suppose the picture is placed, and the eye of the spectator, and the point to be transferred to the picture. To know this point we must know three things. First, the perpendicular distance; that is to say, the distance which the spectator must travel right onwards on a line perpendicular to the picture, in order to have the given point on his right or left hand. Secondly, the off-set, as we shall call it; that is, the distance right or left which he must then travel in order to arrive under or over the point. Thirdly, the height or depth of the point above the eye. To lay down the point on the picture, proceed as follows:—Let the distance of the eye from the picture be made the representative of the perpendicular distance of the given point. On that scale set off a representation of the off-set to the right or left of the centre of the picture. Then set off, on the same scale, a representation of the height or depth of the point, upwards or downwards from the end of the off-set just laid down. For example, the perpendicular distance of a peak from the eye is 10 miles; its off-set is 5 miles to the right; its height above the eye is 3 miles. The distance of the eye from the picture is represented by 20 inches. If 20 inches represents 10 miles, then 10 inches represent 5 miles, and 6 inches represent 3 miles. Set off 10 inches to the right from the point of the picture opposite to the eye, and then 6 inches upwards. The upper end of the 6 inches is the position of the peak on the picture. The demonstration is as follows:—Suppose the picture moved backwards away from the spectator, enlarging as it goes, until it passes through the very point to be laid down. This point is then its own picture, and its perpendicular distance is the distance of the picture from the eye, while the off-set and height on the picture are the real ones. Now bring the picture back again, contracting as it returns, and by the time the real perpendicular distance has been shortened into the intended picture-distance the off-set and height will have been proportionally shortened, and will of course become the picture off-set and the picture-height. Now to the second point. If any number of lines be in one plane their vanishing points are all in one line, namely, the vanishing line of that plane. And if a line in the plane be parallel to the picture its vanishing point is infinitely distant, and the picture proportions for that line are the same as in the original. On these two things the whole depends. Take the given line, in which are parts AB, BC, CD, in any number we please; let the vanishing point be V. From A draw any line at pleasure, and take on it a point W for its vanishing point. Then VAW represents an infinitely extended triangle, to the plane of which VW is the vanishing line. Through either of the points, say D, draw a parallel to VW, cutting AW in E. Then DE has for its original a line parallel to the picture. Draw WB, WC, cutting ED in b, c. These last-drawn lines have originals parallel to that of AE, whence the originals of AB, BC, CD are proportional to the originals of Eb, bc, cd—that is, seeing that ED is parallel to its original, to Eb, bc, cd themselves. Hence the originals of AB, BC, CD are in the proportions of Eb, bc, cd. From this anyone may invent the construction necessary for dividing any line perspectively into parts of any proportion.

NOTES AND COMMENTS.

THE alteration of the Brighton Town Hall has become a necessity that can no longer be put off. The subject has been under consideration for the last twelve years, but the inconvenience of the building is almost unbearable. It will be necessary to rearrange all the offices and provide ample and suitable accommodation, to provide additional committee-rooms, to enlarge the Council chamber, and to provide suitable ante-rooms. The cost is estimated at 20,500*l*. It is also necessary to erect new buildings for police courts and offices, which will cost 24,000*l*., a fire-brigade station costing 2,500*l*., and buildings for a retail flower and fruit market, amounting to 6,500*l*. Altogether the expense on building will be 53,500*l*.

THE Stadthuis, or townhall, of Louvain is one of those buildings that is accepted as exemplifying the poetry of Gothic architecture. It was commenced in 1448, and the exterior was completed in eleven years. The designer was MATHIEU DE LAYENS, whose plans were modified by GILLES PAUWELS. The building seems like a simple cubic block that was made a thing of beauty through the influence of the sculptor's art. Although without a tower and of moderate dimensions it is a worthy rival of any of the Belgian townhalls. It is impossible to have so much delicate carving as appears on the exposed faces in a continuous state of perfection. About sixty years ago a restoration was undertaken, and it is not easy to discern between the new work and the old; both are now in a corresponding state of decay. Without its townhall Louvain would not have much interest for the world, and therefore the municipality have decided on a costly reparation. There is no use in hoping that a conservative policy will be adopted by those who direct the works, for the fifteenth century work may be said to have vanished. That so much picturesqueness has survived in spite of renewals suggests the spirit of the original design.

THE Italian engineer, ENEA LANFRANCONI, who was associated with the improvement of the Danube, and who lately committed suicide at Pressburg, was an enthusiastic collector. He possessed about 14,000 prints, and sketches of which 5,000 were by Hungarian artists. His library contained over 3,000 works, most of them illustrated, and all of great rarity. There are also about 300 paintings, including examples of the Italian, Spanish, French, Flemish and Dutch schools.

MUCH remains to be done before the humbler classes of the population can be persuaded that glaring chromo-prints, which a South Sea Islander would scorn, are not the best adornments for their homes. A lecture on the subject was lately delivered by Mr. L. R. CROSSKEY, in which he stated that benevolent people seemed to forget that there was a legitimate demand on the part of the people for pictorial work and ornament at prices within their means. By means of mechanical processes works of art could be made known and familiar to the great struggling mass of humanity, and their art instincts cultivated by the dissemination of art work—not, indeed, of the highest artistic form, yet of a sound and healthy character. There was, he asserted, a general timidity in artistic circles to countenance any work in which mechanical methods of an economic character were employed for the purpose of meeting popular demands. He advocated the establishment of technical art schools distinct and apart from schools of art, the work of these schools to be mainly in giving a knowledge of the various methods of reproduction and the general principles that govern the technicalities of a trade, and the art instruction to bear directly upon the requirements of particular art industries. He described a school which had been founded on these lines by the governors of the Glasgow and West of Scotland Technical College in response to an appeal made by several trade

organisations. It was established in a small and tentative manner, and had now reached its third session, with over 300 enrolments and a teaching staff of nearly twenty masters. This rapid and extraordinary development showed clearly that there was an eager demand among artisans for this class of instruction. In conclusion, Mr. CROSSKEY said that in spite of free picture galleries, schools of art and art lectures, the gaudy grocers' chromo-lithograph and German print would still occupy places of honour on the walls of the artisan's house, and would continue to do so until the artistic talent of the country was in a position to acquire and use the technical knowledge necessary for making their designs applicable for the varied mechanical methods of reproduction.

THE sixth edition of Professor BANISTER FLETCHER'S "Quantities" (B. T. BATSFORD) is very much larger in size than its predecessors, for there are in it 430 pages. Additional drawings are also introduced. Among the additions are plans and materials to exemplify "the complete taking off in all trades, the abstracting of the various items in the various trades, and the complete bill." Any student who is not able to understand the routine of a surveyor's duty with such precedents before him must be a dullard, and had better seek another occupation. Messrs. LONGMANS, GREEN & CO. have brought out a new edition of the "Treatise on Electrical Engineering for Electric-Light Artisans and Students," by Messrs. W. SLINGO and A. BROOKER. The book was prepared for students of the City and Guilds of London Institute, but it can be useful to a larger number of people. From the excellent arrangement and clear explanations a single perusal of the volume will give a better notion of the theory and practice of lighting than a long study of some other books on the subject. A "Science and Art Series" is being published by Messrs. CHAPMAN & HALL, Limited. One of the latest volumes is a key to examinations in "Machine Construction and Drawing," by Mr. HENRY ADAMS, who is content to give students the benefit of his experience as an engineer. A companion work on "Practical and Plane Geometry" has been prepared by Mr. HENRY ANGELL. The examinations of the Science and Art Department must be deprived of their terrors for novices by cribs of the sort; whether they are as advantageous for the students we need not discuss. As long as they help to increase the number of "passes" the authorities of the Department must approve of them, and hence, we suppose, they are issued by the official publishers. But would it not save trouble and advance the interests of the Department if the examination papers were published some months in advance? Whatever kind of book is studied, a good English dictionary should be found beside the reader. Messrs. BLACKIE have published a new edition of their "Student's Dictionary," which for quality and cost is unparalleled. Their dictionaries have long ago gained approval by their accuracy, and in the latest example we have about 800 well-printed pages with wood-cuts for a few shillings. Unlike the majority of works of the class, this edition presents definitions of architectural details which are correct.

ONE of the pictures which will give interest to the next Salon exhibition will be that by M. JEAN PAUL LAURENS, with the following long title:—*The Inhabitants of Toulouse, after the First Siege, sustained against Simon de Montfort, Rebuilding the Walls of the City which had been Demolished by the Enemy.* The work measures about 29 feet by 23 feet, and is to be placed in the Hôtel-de-Ville, Toulouse. The picture will not only have interest, like all the works of the artist, from its composition, but on account of its execution. It is in distemper, which it is needless to say is the most ancient form of painting. As old HAYDOCKE says, "In distempour the colours are ground with water and grounde with glew, size or gummess of diverse sortes." M. JEAN PAUL LAURENS'S works in oils have been rather sombre, let us hope a change will take place in his works in tempera. In order to gain effect he has employed in places a sponge to lay on the colours instead of a pencil.

THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Association took place on Friday evening, Mr. E. W. Mountford in the chair. Mr. SINGER read a paper on

Brass and Iron.

Mr. SINGER, in the course of it, said:—Wrought-iron is almost the only metal that can be welded together, which means that when brought to nearly a melting-point, which is known by the sparks coming from the fire, and after some silver sand has been thrown in the fire to prevent oxidation from the air coming to it, by great quickness of action the two parts are brought together, and by smart hammering they become united in one solid piece. For this process three things are necessary, good iron, good clean coal and a skilful and quick workman. For fine work our anvils are put quite close to the forge, as small fine work cools even in the transit of a few inches.

It is this quality which gives to wrought-iron its great charm as a metal for ornamental work, a charm that is all its own, and enables the smith to produce work which can be carried out in no other metal. No metal so repays a skilful workman as wrought-iron, and in no other material is, I think, the distinction so evident as the stamp left upon it of good or bad treatment. The smith must model his forms while the iron is hot, and no amount of after-cutting and filing will produce that free and artistic feeling with which a good workman impresses his work.

There are many varieties in even the subdivision of wrought-iron, the merchant from whom we purchase this metal having on his list eight sorts of wrought and fourteen kinds of steel, the wrought-iron varying from 6½ 1cs. up to 22½ a ton, the steel running from 12½ to 68½ a ton. Each of these would have a different brand or mark, each of the varieties being the production of a special firm.

To insure good iron being used it would be well for every architect to know the hieroglyphics on it, as the appearance of bars at 6½ 1cs. a ton is much the same as that costing three times the amount. Thus the cheapest iron is Welsh, having "A" and a crown impressed on the bars; the next is that having "N H & S" with a crown, this being Staffordshire, costing 7½ 5s. a ton; the next quality has Netherton Best, with a crown between the words; after this, comes the old brand of "B. B. H.," this is 8½ 1cs. a ton. "S. C.," with a crown, is very fine iron at 10½ 1cs. a ton; charcoal iron has the letter "L" in a circle, this being 17½ a ton, and is used for cylinders, boiler-plates and engine-iron, where great tenacity is required.

The subject of the value of iron for constructional purposes is beyond the scope of my paper. In this capacity it forms part of the anatomy of architecture, with which you are only too well acquainted.

I cannot speak with enthusiasm of the examples where it has been used by itself and for itself, such as the well of Quentin Matsys, all such having a tendency, in my opinion, to look meagre and poverty-stricken. It is where it plays a more unassuming but useful rôle as an accessory or adjunct to a building that it finds its best expression. Within this limitation quite enough field is left to tax all the energies of the metal-worker. Its strength, durability (if properly treated) and the way that it lends itself to every method of manipulation are the qualities that specially commend iron for application in connection with architecture, for screens, grilles, gates, lighting purposes, door fittings, &c. Very numerous are the other uses for ironwork in a building, and quite equal in number are the possibilities in the way of decoration, and I think it will be admitted that when treated by a master hand the metal never looks obtrusive or vulgar, but that it gives additional value and interest to the old work. In door fittings, for example, what force and vitality there are in some of the old hinges, from the almost plain strap, with its few vigorous marks, to the forged and chiselled masterpieces of the twelfth, thirteenth and fourteenth centuries. Possibly our modern smiths will never excel them.

I venture to hope, however, that in another branch, namely, screens, we may yet make some advance. The old smiths laboured under some disadvantages in this respect compared with ourselves. They had no machinery as we have for producing bars of all shapes and sizes, or sheets of every thickness

and dimension. Thus for large screens they had to fall back upon wood and stone. I do not wish to decry either material for this purpose, but I think there are often occasions when a screening off is necessary without obstruction of light or division of the perspective of the building. Then I venture to say that iron is essentially the material for the purpose. Screens may be made to exhaust all the resources of the metal-worker—forging, chiselling, piercing, repoussé work, enamel and addition of various metals, mouldings of all sections, and tracery, scrolls, and leaf-work of every kind. I need not mention that several eminent architects have drawn attention to this interesting subject, and I little doubt that it will receive still more in the future. Iron has found its last and not least appropriate application in connection with the electric light. I fancy the artists of the Middle Ages and the Renaissance would have fairly revelled in the various treatments suggested by this triumph of science. The delicate treatment that this mode of lighting seems to demand from its very nature, needing no tubes and very little support, is just the scope that calls for the playful display of fine wrought-iron work. I often think we are too serious in our ornament, and give it too laboured an effect, as if it had been designed and wrought after most painful and serious consideration.

There are several features that should make us hopeful of the future of ironwork in this country, namely, the attention now given it by architects, also the help now rendered it by science, so that good iron and steel can always be obtained with care in selection. I think I am also justified in saying that many of our smiths have attained a wonderful amount of skill. No doubt what we most lack is the taste, or instinct, for what is within the power of the material. Also probably we are only gradually learning how much of the work should be done within the glare of the smith's fire, and how careful one has to be not to take the life out of the work afterwards. One great evil we have to contend against is the hurry and drive of the present day, which does not always leave the worker time to work with all the loving elaboration as of old. But when all is said that can be against the present condition of things, I still think that we ought to be in a condition to produce ironwork in harmony with the best architectural products of the epoch.

I must now say a few words upon the subject of brass. From an artistic point of view this metal does not hold so high a position as bronze, as it is inferior to the latter in many important qualities. Its colour is not so good, its contraction in casting is greater, and in a molten state it does not run so freely into the mould; also it is not so satisfactory a metal for the chaser to manipulate. Still, it is the better known and most-used metal of the two, one reason being doubtless that it is cheaper, unfortunately a most important consideration in these days. Bronze is the metal in which the sculptor usually reproduces his work in metallic form; brass, on the other hand, being the metal we see around us in the numerous objects of everyday use.

Brass is a compound alloy of the two metals copper and zinc, bronze being an alloy of copper and tin; and it is difficult in any historical account of these metals to distinguish clearly, which is intended in any earlier mention of brass than 1721, when zinc was discovered, or rather produced by Henckels, as a commercial metal. But the word brass has been used far longer than this idea of the metal as is now understood by that term, and the name for it has been supposed to come from the Spanish word "brasas," meaning the colour of flame, our word "brazen," with its many meanings, no doubt being derived from the glaring appearance of the polished metal. This metal differs greatly in its history from iron, as casting in the latter has been the last development of its use and application, whereas with brass and bronze that was the first form as to the employment of these alloys, and all the earliest finds are the result of casting as the most ready application for their use, and the prehistoric nations made beautiful castings in bronze, whereas iron was known for over three thousand years before Europeans could succeed in casting it in a fluid state.

That it may be seen how difficult it was to produce large pieces of so-called brass, I may mention that up to the fifteenth century it was found impossible to make a piece of metal which could be hammered out as sheet brass beyond about 2 feet square, whereas now it can be had 20 feet long, but even at this late date the metal was more bronze than brass, from its having tin in its composition. This will be seen from the colour of the piece of metal I can show you, and which I have had polished so that its red colour may be seen.

It may here be noted that a little confusion has been caused by some workers of the present day terming the metal in which they engrave memorial tablets "latten brass." This, of course, is a misnomer, as it is merely a repetition of the same word in two languages, as the old French word for brass was "laiton." The metal was so costly that in the sixteenth century they often destroyed earlier memorial brasses by turning them round and cutting the new designs on the back of the older ones.

Brass-work, strictly so called, was not attempted in England before the time of Henry VII., and the railing round his tomb in Westminster Abbey was soon after made, the trade getting general in the time of Elizabeth, who encouraged workmen from the Low Countries to come to England. Yet in 1649 some large works established at Esher, in Surrey, proved a failure, ending in ruin to the founder. The next attempt was in 1678, when the Prince Rupert Mills were started. Then came some works at Hackney, called the Temple Water Mill Works, water being used to drive the hammer, this being before rolls were invented. Up to this time brass was only produced by using calomine and melting copper with it, but in 1721 pure zinc was produced, and great changes took place soon after in the manufacture of brass.

As already stated, this metal is a mixture of copper and zinc, and these are run together in a state of fusion in various proportions, to form the many kinds of brass that are needed—copper being the chief part of the alloy. The Japanese are said to have 200 varieties of these alloys, according to the colour they desire in the finished metal.

The zinc group gives 5 parts copper to 1 of zinc to obtain rich sheet brass; 4 parts copper to 1 of zinc for pinchbeck brass; 3 parts of copper to 1 of zinc for Dutch metal; 2 parts copper to 1 of zinc for ordinary yellow brass; 1.75 parts copper to 1 of zinc for pale brass; 1.25 parts copper to 1 of zinc for dipping brass; 1 part copper to 1 of zinc for hard solder, it being understood that the more zinc is used for the alloy the cheaper is the metal produced, and the less durable it becomes.

Although my remarks are upon brass, it may be well to give the alloy of copper with tin, *i.e.* bronze, as these metals are so closely allied. 20 parts copper with 1 of tin gives a rich red metal; 10 parts copper with 1 of tin gives the best form of bronze; 4 parts copper with 1 of tin gives bell-bronze, which is brittle, and unfit for any other use. The best metal for taps, cocks, &c., is composed of 4 parts copper, 1 lead, 1 zinc and $\frac{1}{2}$ of tin. Up to a late period of the last century the manufacture of brass was a slow and tedious process, taking at least twenty-four hours, as they used the carbonate of zinc, or calamine, with the copper, in taking that time to reduce the ore and unite with the copper; but now that the metal zinc can be obtained in a pure state the process can be completed in about an hour, for as soon as the copper is melted the zinc is then added, either in a molten state, or is plunged down to the bottom of the molten copper, and then well stirred, or in the casting the zinc, being the lighter metal, will be found too much in the upper part of the casting.

Any of the above alloys can be easily cast, but no ornamental work or any object—excepting plain block ingot can be cast in copper alone, the contraction of this metal in its pure form being so great that, when cooling from the molten state, it pulls itself to pieces when anything prevents that contraction. The difficulty attending contraction will be seen when I mention that the base of the statue of Lord Napier contracted just over 1 inch, and if provision had not been made for this, this mass of metal, weighing nearly half a ton, would have pulled itself to pieces in cooling.

The Chinese have a clever method of reducing the effects of contraction as much as possible, by making the flask in which the casting takes place to contract in an equal degree with the molten metal, thus keeping the mould close to the metal, and by this means getting a sharper result.

Brass is very tenacious, but it has this defect, that if the tension is continued, a singular molecular change takes place, rendering it rotten and most unfitted to support any heavy weight. This fact was evidently known to the brass-workers of the sixteenth and seventeenth centuries, for it will be noticed that they never used brass to suspend the large brass chandeliers made about that date and so often seen in our churches, but invariably used iron rods. It has been said by an authority that every brass pendant hung by means of brass supports will drop within fifty years. This may be an exaggeration, but brass is not a suitable material for the support of any heavy object.

Brass is the metal in which a very large proportion of what is known as objects of applied art are now produced, bronze being retained for fine art. And to bring it into suitable shapes, brass is cast, drawn into round wire, flat strips, hollow tubes, and rolled into sheets, and in these various forms easily lends itself to the manipulation of the workman.

There is now no time to more than just refer to the long series of operations through which this metal passes in its many different modes of treatment. Thus in a molten state it is cast into suitable forms moulded in sand. The model from which the mould is made may be either carved in wood or modelled in clay. The castings, according to their shape and the object for which they are required, are either turned in a lathe or are chased. Brass is also beaten into form or embossed, bent into scrolls of various kinds, when in the shape of strip brass, and also there is the large subdivision of engraved work.

Mention should also be made of the process known as

spinning. The form of the object that is to be spun is first made in either hard wood, or if a great number of the article is required it is made in metal. This form, which is termed a chuck, is put in a lathe, and against it is fixed a brass disc. The lathe is then put into rapid motion, and various steel tools of different shapes pressed with considerable force against the disc, beginning in the centre and gradually working outwards as the metal yields to the pressure and takes the form of the model. It is a very interesting process, and astonishing how quickly a good workman can spin a number of forms, which, if they had to be hammered up, would entail much time and labour.

Brass is also used for repoussé work, and this process is perhaps the one that requires the most highly skilled and artistic treatment of any through which the metal passes. It is not quite such a suitable metal for this purpose as copper, as it is not so soft and cannot be stretched so easily without cracking, but this method of execution has been, and still is, very generally employed for converting this metal into ornamental forms, the processional crosses on the table being interesting examples of the application of repoussé work.

After brass has been treated in one or other of these processes it is either polished or dipped in an acid solution and burnished, to give the metal its bright yellow colour, with which we are so well accustomed.

As brass cannot be welded like iron another mode of attaching the various parts of a piece of work has to be adopted, and as may be imagined from the general use of this metal for the manufacture of ornamental forms, this process, which is known as soldering, is not a difficult one. The two surfaces are united by the application of sufficient heat to melt a more fusible and baser metal which is introduced between them, and which combines with both and firmly unites the two parts.

It will thus be seen that many industries throughout the country are the result of the many processes through which this metal passes before it comes before us in the form of, say, a lectern or an altar-cross for our church, a gas-bracket or an electrolier to light our room, a door-handle or a fender, and perhaps no metal has a more universal application, as it is used for almost every form of ornament needed in metal for either ecclesiastical or domestic purposes.

As brass is a metal that easily tarnishes, it has been found necessary to coat it with a thin substance to preserve it from the effect of the atmosphere. This is termed lacquer, and is a thin, transparent varnish put on the metal when hot. If the object could be kept from moisture being deposited upon it, and be occasionally wiped over, there would be no need of its being lacquered, but as this does not seem possible the work is usually lacquered, and not always with satisfactory results, for you must often have noticed the dark streaks upon memorial brasses, the reason being that generally such work is in a church, of which the heat is only raised on the Sunday. The air then gets warm much sooner than the brass, which is on a cold wall, the wall taking a long time to get its temperature raised, and during this time the moisture is deposited on the brass. This cannot be absorbed as on the surface of the walls, and the moisture runs down the brass, producing streaks on the metal, which are caused by the lacquer being destroyed by the damp. The better plan, I think, is not to lacquer a memorial brass, for it should not be difficult to find willing hands who about once a month will give such work a few minutes' attention, and this would be sufficient to keep the metal a good colour.

It is a question if it would not be desirable to make a larger use of bronze in preference to brass. I confess that for many purposes I consider the former the best metal. Thus, for work in churches, I think bronze the better material of the two. It is more durable, of a richer shade and it retains its colour much better, as brass so easily tarnishes on account of the zinc in its composition, and the difference between the cost of the two metals is really little; in fact, our firm is always willing to supply bronze at nearly the same price as may be quoted for brass. I believe in the future bronze will be much more generally used than it has been in the past.

The application of brass to architecture is not quite so direct as in the case of iron; as brass, being cleaner to handle, and no doubt also because of its colour and the facility of its manufacture, is more often used for movable pieces of furniture, such as lecterns, candlesticks, crosses, vases and numerous articles in daily use.

It is now recognised, however, that even a piece of furniture has its influence upon a building, and deserves and repays the architect's attention. It is admitted at the present day, however it may have been a few years ago, that it is hardly expedient to turn the architect out of the house as soon as the four walls are built.

Moreover, almost every fixture applicable for iron has also been made in brass, with more or less success, the adoption of the latter giving a more luxurious effect than the harder and less costly metal. We all know the rich appearance of the fine

old coronæ, with their little turrets and rich bands of ornament, which date back to very early times. Triumphs of art were the old brass shrines on which devout Christians lavished their best efforts, and although so elaborate, they do not give the idea of laborious execution, but almost spontaneous growth. Abroad I notice that brass altars have often been produced in recent times; they are very rich in workmanship, and may perhaps with advantage be adopted in this country. I think in the later French styles the glitter of the brass pendants and brackets greatly contributes to the very finished and furnished aspect of the period.

England is perhaps not so rich as some countries in examples of old brass-work, but there is a certain dignity of style about such as we have; for instance, the old brasses and lecterns, which have been revived with some success.

Mr. GARBUTT proposed a vote of thanks to Mr. Singer for his paper, and referred to the superiority of Oriental and Indian work, including Japanese work.

Mr. STOCKDALE, who seconded the vote of thanks, expressed his preference for brasswork rather than bronze.

Mr. SATCHELL regretted that so few members were present. He alluded to a difficulty, that lettering would not stand on bronze tablets used externally. A different treatment in two colours would render the lettering legible. Another question was that modern wrought ironwork did not hold its own against the old work.

The PRESIDENT said ironwork for screens was seldom satisfactory, and could not even feel satisfaction in some of the beautiful work designed by Mr. Pearson. To make use of it for grills good results could be obtained.

The PRESIDENT, having put the vote, it was carried by acclamation, and Mr. SINGER briefly responded.

Very few members were in attendance, a fact which the President called attention to, but did not give any reason for, though a reason was probably not wanting, as members of the Architectural Association enjoy no special immunity from colds and influenza.

THE WAVERLEY STATION HOTEL COMPETITION.

THE following is the full text of the remonstrance which Dr. R. Rowand Anderson has addressed to the Secretary of the North British Railway Company concerning the recent competition:—

16 Rutland Square, Edinburgh:
February 23, 1895.

Dear Sir,—I duly received your letter of the 19th, written in reply to mine of the 16th inst., and I have to express my regret that you have not replied to the question put in my letter.

In your letter of the 14th you stated that the designs for the proposed new hotel and offices at Waverley Station had that day been carefully considered by the directors, and you intimated their decision on the plans submitted. On the 16th I wrote you asking if the directors had the plans, sections, reports and estimates examined by experts before coming to a decision; and, in reply, you have referred me to the conditions set forth in your letter of October 26 last, under which various architects were invited to submit plans. It is needless to say that I had referred very carefully to that letter, which contained minute and particular directions requiring to be observed by the competitors as to the methods of arranging and placing the building, the height of the building at various points, provisions for communication between different sections of the building, and other very important matters affecting the designs. The letter of instructions stated that the directors should be the sole judges of the designs, but did not suggest that the directors were not to adopt the only possible methods of forming a judgment.

The circumstances connected with the competition and the decision of the directors have been so extraordinary, that I think an explanation is due alike to the competitors, the architectural profession and the public; and it was in the hope that some explanation would be offered that I addressed you on the 16th.

When architects enter into a competition they know that only one competitor can be successful, and I should never cavil at the result where the designs submitted receive adequate consideration and an honest attempt is made to do justice to the competitors. In the present case it is evident that these conditions have not been observed, and the competitors have the gravest cause of complaint against your directors. Apart from the competitor whose designs have been accepted, five architects of established reputation were invited to compete, and I am justified in saying that they all devoted much thought, labour and expense to the preparation of their plans. I devoted to the work my own time and the time of twelve assistants, working extra hours for eight weeks to the exclusion of other work, and I have no doubt the other competitors must have made

equal sacrifices. It was freely stated to myself and other that we might save ourselves the trouble of competing, as the result was a foregone conclusion; but I declined to believe that the directors of the North British Railway Company would ask professional men to give their time, skill and experience to the preparation of plans without the intention of dealing fairly with them in the award. It is now abundantly evident that the designs have not been carefully considered.

My plans were sent in only on the night of the 11th, and the decision was intimated on the 14th, on which day the designs were, as stated in your letter of that date, "carefully considered by the directors."

The directors had to examine and compare the elevations and plans of six sets of designs for a block of buildings to consist of a large hotel, railway offices and shops, requiring to be adapted to an exceptional site, and it was part of their duty to the competitors to take proper means of satisfying themselves that the different designs were in conformity with the instructions issued, and that the actual conditions as to available space, height and other important details were observed. In dealing with designs for a work of such magnitude, involving the consideration of the grouping and arrangement of hundreds of apartments, the directors ought, in ordinary course, to have had expert assistance and advice alike as to the more purely architectural quality of the designs and their practical adaptability to the purposes to which the buildings are intended to be put. The schemes of arrangement of the interiors alone (without speaking of the elevations) had taken weeks of thought and planning on the part of each competitor, and it was a matter of absolute physical impossibility for any one, even an expert, to master the details of the several schemes within the time that elapsed between the sending in of plans and the award.

By whatever process the decision of the directors was arrived at, it certainly was not reached by the only proper course of considering each set of plans in detail and comparing them with each other. Even if the directors were, unaided, competent to make such examination and comparison, it is quite evident that they did not attempt to do so.

As a practical man, acquainted with the difficulties of the task, I have no hesitation in saying that the directors, when they gave their decision, were necessarily ignorant of what they were dealing with beyond such vague ideas as they may have been able to form from a pictorial representation of the buildings, and I say that it is disgraceful to treat in such a way men who have attained a position in a honourable profession. The directors could have entrusted the work of designing the building to any person they pleased without going through the solemn farce of inviting competitive designs. Having invited competition they ought surely to have allowed a decent and sufficient interval for the adequate consideration of the designs to elapse before announcing their decision, instead of adding the insult of a public slight to the injury inflicted on the competitors, whose labour, thought, and outlay have been wasted.

The annals of architectural competition have many chapters of injustice, but I have never known of a competition conducted with such a contemptuous disregard of even the ordinary forms of fairness. I am quite aware that I lay myself open to cheap sneers about the disappointment of unsuccessful competitors, but I am satisfied that a piece of gross and wanton injustice has been perpetrated, and I shall not allow any fear of misrepresentation to deter me from offering my strong and earnest protest against what I consider injustice and insult to the architectural profession.

I request that you will submit this letter to your directors, and I remain, yours faithfully,

(Signed) R. ROWAND ANDERSON.

The Secretary, North British Railway Company.

THE ACOUSTICS OF BUILDINGS.

AT the recent convention of the Ontario Association of Architects the subject of acoustics was discussed. The *Canadian Architect* gives the following report of the conversation:—

The president, Mr. Edmund Burke, said one method he had found very effective was to have a flat wall behind the speaker. He had known instances where by reason of an octagon form behind the speaker the echo had been such that he could hardly be heard, and this was in a great measure remedied by cutting off the octagon.

Mr. Wickson inquired if there was not some theory about the ellipse being the most perfect form; he had been given to understand that it was, although he had not found any authority for the statement.

Commander Law remarked that the Mormon temple at Salt Lake City, Utah, was said to be almost perfect in its acoustic properties, and was shaped like half an egg.

Mr. Edwards added that the form of the pavilion at Grimsby Park was suggested by the Mormon temple referred to by

Commander Law, but although, as that gentleman had said, the Salt Lake building was believed to be acoustically the most perfect on the continent, the Grimsby imitation bore the reputation of being the very worst in that respect.

Mr. Wickens said he had heard it remarked by a musician that any building which was good to speak in was poor to sing in. It seemed almost universal that a church or any building which pleased singers was not one that pleased speakers.

The Registrar suggested that if the choir was placed in a recess of resonant wood above the level of the speaker, he would not be affected.

Mr. Baxter said the objection to seating the choir in a groined recess behind and above the speaker was, that it formed a volume of air behind him which he had to maintain in vibration all the time he was speaking, and which weakened the sound. The higher the recess could be raised behind the speaker the better. He had noticed one church in which the choir was directly above the speaker, the front of the choir gallery being brought out about 4 feet, the under side of it forming a cove, which to a great extent kept the sound vibration directed from him out to the audience, and leaving a clear and sympathetic vibration which did not affect the main church at all.

Mr. Edwards agreed with the essayist that it was difficult to formulate any definite laws on the subject of acoustics; it was a case in which "doctors differ." The whole theory of wave sound was doubted by some, who adduced very good reasons in support of their unbelief, contending that it takes so much effort to set in motion the atmosphere which is the means of communication, or which is the matter on which the wave sound has to act. As an illustration of that they contended the distance the sound of a grasshopper is heard would require tons of power to produce the wave sound at such a distance if the wave theory were correct. That being the case, it was necessary to look carefully at the beginnings on this subject, and to avoid building up any superstructure before the foundations were securely laid, and he thought the foundations of the matter required some further negotiation yet.

Mr. George Browne related his experience of a church in Winnipeg which on account of its great height was very defective in acoustic properties, and in which it was almost impossible to speak effectively. It was at last decided to take down the building and re-erect it on the same foundations, but with the height greatly reduced, and after that was done the pastor stated that whereas the old church was one of the very worst he had spoken in, after being so rebuilt it was one of the very best. He thought this demonstrated that not only length and width, but height also, had a very important bearing on the subject of acoustics. He had this summer completed a Presbyterian church, which was built exactly square, about 65 feet square, in which he had adopted the American system of placing the preacher in a corner. It had a gallery on two sides and coved plaster ceilings, and the tie beams formed deep panels in the ceiling. The result had been one of the finest buildings for speaking in the city, so much so that whenever religious meetings were held requiring a building with good acoustic properties, the persons interested tried to get this church to hold them in. In the Convocation Hall of Manitoba College they had a hall 65 by 35 feet, and he was told by the principal that he found no difficulty in speaking in it. There was a gallery at one end of the room and a coved ceiling. From his experience he believed that the coved ceiling aided very materially in causing the sound to travel freely throughout the hall.

Mr. Wickson asked if a coved ceiling at the end of an audience room opposite the speaker had the effect of causing an echo.

Mr. Browne said he always continued the cove all around the building; he thought it reflected the sound.

Mr. Baxter said he had observed in nearly all the Chicago buildings that the cove on the rear wall was far deeper than around the sides; in fact, they drew the cove line right round so that the entire body of sound was directed right down, and there was no chance for the formation of an echo, whereas if there were any straight line between the curve and the floor of the gallery, it would not have so good an effect.

Mr. Paull said an important matter was what should be the limit of size in a church in order to secure proper acoustic qualities. He had heard it said that 1,200 persons was the greatest number that could be accommodated so that the preacher could command their hearing. The church in Winnipeg spoken of by Mr. Browne as 65 feet square would have about that capacity. He would like to ask Mr. Browne how the extremities of the panels in the ceiling of that church were finished. Were they coved at the ends?

Mr. Browne stated they were finished simply by running up a false rib. The tie beams came across and then they ran them down on the cove to a small projecting cornice.

The President stated that in regard to the remarks of Mr. Edwards about the grasshopper, he thought it was necessary to take into consideration the number of vibrations in the air;

he supposed the more rapid the vibrations of the air the more penetrating the sound would be.

Mr. Edwards said he had not the confidence in coved ceilings that had been expressed by some of the members. He had in his mind a large room or auditorium which was almost as bad acoustically as the Grimsby temple, the ceiling of which was very deeply panelled and with a very extensive cove and all the other features which had just been pronounced of no great advantage. It was really a most miserable place to speak in. At one time the platform was placed on the long side of the building, but the echo was so bad that it had to be changed to the other side, which produced slight improvement, though it was not perfect by a great deal yet. These things did not always work in accordance with one's preconceived ideas. He had happened to have a building somewhat similar to the Winnipeg church rebuilt by Mr. Browne, and he had recommended putting in a gallery, which he hoped would remedy the trouble that existed.

Mr. Browne said he regarded a gallery as necessary to secure good acoustic properties in a church. Another matter he wished to mention was that the windows in Westminster church had circular heads, cutting into the cove, just the same as a vault or groin, and he would not at all wonder but that assisted the sound.

Mr. Edwards said one of the best auditoriums he had ever been in, speaking from the acoustic point of view, was the Casino of New York, which was built very much after the style of the Massey Hall in Toronto, only the recesses were much deeper all round. This had a very beautiful effect from the artistic standpoint, as well as being very beneficial to its acoustic properties.

The President said that in view of Mr. Browne's opinion that a gallery was necessary to good acoustic properties in a church, it would be interesting if anyone could tell what had been the effect in St. James Cathedral in Toronto, from which the galleries had lately been removed. He thought an instance of the detrimental effect on good acoustics of a high ceiling was to be found in the chamber of the Parliament Buildings in Toronto, which was one of the worst rooms possible for hearing in.

Mr. Wickson suggested that that might be due to the influence of having been designed by an American architect.

Commander Law asked if the Massey Hall was regarded as a good building acoustically, and what effect the "gingerbread" work had on its acoustic properties.

Mr. Edwards said he had no knowledge of the acoustic properties of the building referred to, and had only spoken of it with reference to its structural resemblance to the New York Casino.

MODERN FRENCH ARCHITECTURE.

IN addition to various interesting articles on engineering and social subjects, the *Engineering Magazine* for March contains one on "Recent Architecture in France," by Mr. Barr Ferree, which is abundantly illustrated. We take the following from it:—

The most distinguishing characteristic in current French architecture, the element that may be seen in almost every building, the quality that may be noted in every locality, is the adaptability of the structure to its purpose. If it is a school building it is a school and nothing more. If it is a town hall it is as unmistakably that, and is as elaborate a piece of architecture as the appropriation made for it permits. If it is a great palace or an expensive museum it partakes of the natural character of these structures. In business buildings alone is this nice balance sometimes lacking. If funds are short the building is correspondingly simple; if they are ample it is correspondingly rich. There is always a careful adjustment between funds and purpose and architecture that the people of other lands would do well to ponder over and profit by. Those American institutions—and several might be named—that have projected costly palaces for themselves with only a fraction of the necessary funds in hand are proceeding upon a principle of economics in architecture that no Frenchman would venture upon. But this is one of those common-sense procedures in French architecture that our importers of that commodity have as yet failed to bring over.

The results of this common-sense policy are just what might be expected. The Frenchman does not build for show, unless he is able to carry out his project. He is never afraid to build simply and plainly; nor does he hesitate to satisfy himself with a plain wall—though he will go so far as to whitewash it—if that is all his money will permit him to do. Architectural art often loses by this habit, but there can be no doubt that the French people are gainers by it. Examples of this may be seen in almost every city and town in France. The schools, of which a prodigious number have been built, are excellent types of it. Plain, simple, unpretentious, almost ugly buildings in their absolute want of artistic form, these well-planned, conventionally-

designed edifices must, for all their lack of pretence, be counted among the most important and successful of modern French buildings. For, plain though they be, it is not slipshod building that they illustrate, though in America they might be spurned by the average architect and ignored by the best as beneath the notice of masters of their art. These plain walls, these severe forms, are part of the system on which the buildings are designed. Intended only as coverings and housings for the schools, it matters little what their external form may be if their planning is judicious, economical and wise. That is the real strength of these buildings; their façades are nothing, their plan is everything.

There is much wisdom in such a system, but it is not applicable to every sort of structure. A plan is not a building, though it is a good start and an essential foundation. But if modern French architecture had nothing to offer but these formless schools and kindred buildings, the system under which they are produced would soon topple off its lofty perch on the apex of architectural art in the nineteenth century. We may regard the absence of architectural features as admirable in buildings where their presence would be a superfluity or where the funds in hand will not permit their use, but we require more than a plan to satisfy our conception of modern architecture as an art. Yet the disdain with which the elevation is frequently treated in these elementary structures sometimes appears in more pretentious works, for in these too frequently the façade fails to equal the plan in excellence, and students at the school make no secret of the fact that the larger part of their time is given to the study of the plan, the elevation being left until the last, when it is, as it were, pitchforked upon payer and regarded, apparently, as the product of inspiration rather than as the result of profound study and careful thought.

If one sees many buildings in France that interest only by their severe insistence on commercial or financial requirements—and these are not what we call commercial buildings in America, but schools, manufacturing establishments and the like—one is not less astonished by the prevalence of bad buildings. For one masterpiece there are a thousand horrors—a truly extraordinary state of things for a country which not only affects to lead the world in art, but which supports a great school of architecture for the creation, maintenance, and preservation of an architectural standard. We may look upon such a condition at home with a certain equanimity, since we can always console ourselves with the thought that we know no better. But France! Surely if anything is admitted in modern art it is that they do things better in France than in less enlightened countries. And yet if all the pretentious buildings erected in France in the last twenty years could be gathered in one single exhibition—barring such extraordinary masterpieces as the Opera House in Paris, the Palais de Longchamp at Marseilles, and one or two similarly ornate structures built under unusual circumstances—the proportion of interesting buildings to bad, of good things to indifferent, would be found very small indeed. That this is actually so cannot, I think, be denied. That it is so relatively leads to but one conclusion—the failure and incompetency of the School of Fine Arts to introduce an architectural standard that its pupils can carry into actual practice.

Suppose, in the list of buildings that might be considered above the average, both by purpose and in cost, there were fifty or even a hundred; what would that be out of the enormous total of other structures erected in the same period? Look at the conditions that surround architecture in France. Elevated to the dignity of a department of the Government, given a costly and superbly equipped school for the training of young architects, provided with every apparatus, given every opportunity, dowered with prizes and rich collections—architecture enjoys opportunities in France that it has in no other land. And when to this we add the natural artistic tastes of the French people, their rich artistic past, their countless artistic monuments, their environment, their skill, their ingenuity, in very truth it would seem that the production of architectural masterpieces would be an everyday occurrence to them, while no trouble at all should be experienced in giving less pretentious structures that grace and beauty they could not have in less happily situated lands. Is it too much to ask for this? Is it too much to look for extraordinary things when men, after all, are but human and accustomed to mediocrity?

Unquestionably it is too much to insist on masterpieces as the solitary product of the school of fine arts. Doubtless it would be both delightful and elevating if such were the truth, but the history of architecture—and the history of French architecture is not an exception—shows that masterpieces are the rare gems, not common everyday affairs. It is true this rule was all but broken during the great cathedral-building epoch in the thirteenth century, and again when the valley of the Loire was dotted with its châteaux, but those were exceptional times that have no counterpart in the present day. And it is further true that the educational work of the school is chiefly concerned with the making of masterpieces on paper, and it might perhaps be in order to ask that some of this skill,

so abundant and so plentiful in student days, should be served up in appreciable quantities in real structures. But, while it may be true from the French standpoint that all its architects are capable of producing masterpieces, very few of them, with the opportunities of producing great buildings that occur more frequently in France than elsewhere, ever actually have the chance of doing something really great. The most they can do is something good, and it is by this they should be judged.

Did time and space permit, it would be interesting to interrupt this discussion for a little dissertation on the geographical distribution of modern architectural monuments in France. If architecture is so important an art in France that the Government can support a costly school for instruction in it, there must be ample opportunities for its graduates to build and cover their land with buildings both interesting and good. Yet I have been solemnly assured by gentlemen who have made their life-work the diffusion of architectural knowledge in accordance with the French standard that it is only in Paris that notable works in architecture are to be looked for. Is it true? I trust not; I do not think so; but at least this statement reflects cultivated and trained opinion on the subject, and saves one the bother of visiting departments in search of modern architecture. But let us, for the nonce, accept it as fact, and study the monotonous streets of Paris.

For Paris streets are monotonous, with a deadly dullness that only London streets of the first part of the century can equal. It is a different sort of dullness, while the older London architecture is dull through lack of form and art and variety, the newer Paris architecture is dull through an affected and attempted variety. They no longer build structures as featureless as those that line in the Rue de Rivoli, or edifices as sober and thoughtful as those that form the Place Vendôme or the Place des Vosges. They do much worse than either style illustrated in these different groups. No house, no structure of any kind, is now erected in Paris that is not plentifully supplied with pilasters, apparently deemed as essential as the windows or the enclosing walls. Every floor must have its balcony carried on stone carved corbels, and railed off with light iron grilles. There must, after a certain height, be a cornice, likewise carried on corbels. And over all there may be one or two storeys, an attic, and a curved roof, or something pieced on to eke out the height. And when we have put casement windows to the openings, and lace sash curtains to these, we have obtained a design in the most approved Parisian style for block buildings. It is simple enough, and, in capable hands, possible of satisfactory and pleasing treatment, but when repeated a thousand times in a single street, and on every cross street and in every part of the huge expanse of Paris, and in every modern street of every modern town in France, it becomes monotonous and sickening. Its possibilities have long since been exhausted; the surfeited student can scarce keep back a cry for something different.

Academic training in architecture may not be directed toward such an end, but this distressing monotony is one of the results it produces. As a natural consequence there is not in all Paris a single restful stretch of wall. What is left of a front, after the windows have been cut in it, is used as standing room for pilasters; or cornices and balconies straggle across it until of plain restful surface there is nothing at all. This would be bad enough were the ornament applied to the walls good and sufficient, but when most of it is very bad, hard, cold, unsatisfactory detail, verging to one or the other extreme, either too coarse and florid or too refined and small, it becomes absolutely intolerable. But the real state of things is much worse than this implies; with all his respect for the past, with his dependence on precedence, with his ceaseless copying, his endless reproduction of past forms, a French architect is never so happy as when he is inventing a moulding or a column of his own, unless indeed it is when he is going further than this, and is making a purely original Order. That most of these newly-manufactured additions to architectural knowledge are wanting in the very elements that make the Greek and Roman Orders good and great he does not seem aware, for whenever the chance occurs he gets busily to work, turning out aberrations and doing his level best to make his work as extraordinary and as individual as he can, doubtless under the impression that he is thereby showing a vast amount of originality and perhaps some little industry and invention.

Recent French architecture is very largely deficient in feeling, and this arises in good part from the hardness and inefficiency of the detail. French architects appear quite incapable, even in their most academic designs, of throwing off their academic training. Their designs want life; they are deficient in vitality and feeling. Is it due to a striving after realities which the designer himself is incapable of producing? Is it due to a lack of appreciation of these qualities in architecture? Or is it due to a simple inability to do otherwise? Possibly all things may have their influence in one way or another, but whatever the reason, the results are clearly in evidence.

The conditions under which architecture is practised in

France apparently have their influence on this use of detail. French buildings divide themselves into three general classes. In one are the utilitarian structures treated in a utilitarian manner, admirable in its severity, though not additive to the beauty of the cities. In another class are ordinary blocks of city buildings designed almost on a single model, calling for little effort at originality or variety on the part of the designer. In the third class are the more ornamental and monumental structures with which the soul of the French architect is delighted, with which the architects of other lands are dazzled, and by which it is to be presumed the architecture of to-day in France is to be measured. But while few really monumental structures are produced, the possibility of their production is present to every one. It is small wonder therefore that the methods to be employed in more pretentious buildings should be employed in less important ones. The richness and overloading of many French designs, the constant employment of pilasters, especially where they are not needed, the introduction of new Orders and the invention of new detail—all these may be but a survival of the idea that every man may design a masterpiece in his day, and his application of these things to every sort of building may only be an effort to keep his hand in.

THE AMERICAN SCHOOL OF ARCHITECTURE AT ROME.

At a meeting held at the Century Club on June 12, 1894, at which the American School of Architecture in Rome was established, the executive committee appointed at the time was instructed to invite certain gentlemen to constitute a permanent committee of managers and to call this managing committee together at a suitable time and place to complete their organisation, and to determine upon the policy in accordance with which the school should be conducted.

The school is founded for the benefit of advanced students, and is designed to further the work of the institutions in America now offering courses in architecture, and thus promote regular progressive academical training. It offers a post-graduate course, open only to the beneficiaries of the travelling scholarships connected with those institutions, to those who have acquitted themselves with signal ability in the examinations for those scholarships, and to members of the Ecole des Beaux-Arts in Paris of at least three years' standing. Other well-accredited students are admitted to certain hospitalities of the School at the discretion of the secretary.

Cornell University, the Institute of Technology in Boston, Columbia College and the University of Pennsylvania have well-established schools of architecture. Harvard University has taken significant steps toward the establishment of courses in architecture and Yale University has them in contemplation. There are at present travelling scholarships at Columbia College, Cornell University and the University of Pennsylvania, and, in addition, the Rotch scholarship in Boston, which is not connected with any institution.

The foundation of the school is an undertaking of national interest, and has enlisted the support and sympathy, not only of some of the foremost educators and members of the architectural profession throughout the country, but of distinguished persons in the community at large interested in the advancement of the arts. The managing committee consists of R. M. Hunt, C. F. McKim, W. A. Boring, W. M. Kendall, Augustus St. Gaudens, J. Edward Simmons, H. G. Marquand, Samuel G. Ward and J. A. Garland, of New York; R. S. Peabody and Martin Brimmer, of Boston; D. H. Burnham and Franklin McVeagh, of Chicago; George E. Leighton, of St. Louis, and the chiefs of the departments of fine arts or of architecture in the principal institutions which maintain courses in architecture, namely, Professor Norton, of Harvard College; Professor Babcock, of Cornell University; Professor Chandler, of the Massachusetts Institute of Technology; Professor Ricker, of the University of Illinois; Professor Ware, of Columbia College, and Professor Laird, of the University of Pennsylvania.

The institution has already developed into an undertaking of much greater magnitude than at first was contemplated. Early last spring a number of practising architects and representatives of institutions of architecture of New York, Boston, Chicago, Philadelphia and elsewhere, met and discussed the most feasible plan for the direction and guidance of the holders of prize scholarships in their studies abroad. Hitherto the beneficiaries of these scholarships have followed very largely their own devices, travelling from place to place, filling their sketch-books with miscellaneous material and sending home but few carefully-measured drawings. These "envois" bear testimony to the diligence of their authors, their facility with pen, pencil and brush, and their evident serious intention. On the other hand, considered collectively, their work has shown no common purpose, and individually little intelligent prosecution along consistent lines. This being a matter of

common observation, the past holders of travelling scholarships are general in their approval of the effort to confine foreign travel and study hereafter to a definite and specific course. These considerations at first led simply to the idea of establishing an "atelier" at Rome with a competent instructor at its head, but the more the matter was discussed the greater became the interest in the undertaking, and finally it was determined to found an institution upon a broader basis—one which in the course of time should equal in endowment and advantages the foreign academies at Rome, although somewhat different in its scope and object.

The school is primarily one of contact and research, rather than of design, aiming at the formation and education of a correct taste and to impress upon the mind, by daily contact with the great monuments, those principles which are essential to the enduring quality in architecture, be the style what it may. Nor does it seem necessary to add that it is not a place of copying, in the sense of collecting "motifs" to be reproduced at home with pedantic exactness. The founders of the school believe it to be essential for the professional architect to study thoroughly and on the spot the best examples of ancient architecture and of such Italian Renaissance as is worthy of being considered its successor. For this purpose the monuments studied will be chiefly those of Rome and Athens, the headquarters of the school being established at Rome rather than at Athens, because of the greater amount of material in the former city of use to the modern student, whether in the art of architecture, of mural decoration, or of the kindred arts. Moreover, too much cannot be urged in favour of a prolonged stay of several years, not only for the purpose of more thorough study, but for the sake of an appreciation of the true spirit of Classic art such as is to be gained no other way.

The School was formally opened under the charge of Austin W. Lord, as secretary, and began its work on November 1 last in eight rooms, occupying the upper storey of the Palazzo Torlonia, on the south-west corner of the Via Condotti and the Via Bocca di Leone, between the Corso and the Piazza di Spagna.

In the absence of settled organisation, it will require another term before the school may be said to be fairly launched, but it is satisfactory to note that of the four travelling scholars this year abroad three have been following the course of the school.

Departments of painting and sculpture are in contemplation, and, it is believed, will be started within a year. Meantime, the committee has been in receipt of numerous inquiries in regard to the condition and purposes of the school, and as to the possible range of its operations. It has been asked what advantages it offers, and on what terms, to students of architecture who are not qualified to become members of the school. Inquiries have also been made in behalf of students of archaeology and epigraphy, whether the advantages of the school cannot be extended to them, and it has been suggested that some sort of co-operation may be practicable by which their interests and those of the school may be mutually promoted. To these inquiries answers have been made in accordance with the resolutions of the committee, and it has been added that any suggestions looking toward the promotion of any interests in any way germane to those which the school has already in hand would be cordially received.

In response to this intimation, notice was given at the recent joint meeting of the Archaeological Institute and other learned societies in Philadelphia that a discussion would be held in the rooms of the University on the afternoon of Friday, December 27, in regard to the possible establishment in Rome of a school of architecture, archaeology and epigraphy. At this meeting, which was largely attended by persons interested in Roman literature and antiquities from all parts of the country, great interest was manifested in this suggestion, and a committee, consisting of Professor W. G. Hale, of Chicago University; Professor Frothingham, of Princeton, and Professor Minton Warren, of the Johns Hopkins University, was appointed to confer with the architectural school at Rome, and to report to the Council of the Archaeological Institute at their meeting in May what they might find practicable and desirable to accomplish.

Meanwhile it has been suggested that the building known as the Casino dell'Aurora, occupying a part of the grounds formerly belonging to the Villa Ludovisi, would afford an admirable seat for such a school or schools, and that it could probably be leased for a term of years for a sum which, though larger than would be needed for hired chambers, might not be extravagant or unreasonable in view of the great advantages offered. The building is situated upon an isolated plot of ground raised 15 or 20 feet above the surrounding streets, and comprising apparently about 80,000 square feet, which is the size of the enclosed space in Gramercy Park in this city. It is on the Pincian Hill, not far from the French Academy in the Villa Medici. The building itself contains about thirty rooms. Some of these are decorated with well-known frescoes, among which is the famous *Aurora* of Guercino. The grounds,

which were laid out by Le Nôtre, are well covered with trees and shrubs and afford ample space for the erection of additional one-storey buildings, should such be required at any time for work rooms or studios.

The experience of the winter seems to show, what indeed was to be anticipated, that whatever advantages the establishment of such a school may bring to students who are in attendance for a short period, the serious study which it is intended to promote is to be had only from those who devote to it serious and long-continued labour, and that such work is not reasonably to be expected except from young men who go abroad with this special purpose in view. This has also been the experience of the American School of Classical Studies at Athens, which, while it has been of inestimable service to the sixty or seventy students of the Greek language, literature, history and art, who during the last twelve years have availed themselves of the opportunities it has afforded, has not succeeded in developing the class of serious workers in archaeology which it is the ultimate purpose of such a school to create. The managing committee of the Athens School are accordingly now taking measures to establish special scholarships, to be held on the condition that the beneficiaries shall spend twelve months in prosecuting their studies in Athens and other Greek lands, under the direction of the school. It has become plain that the main object of the Roman school enterprise can be compassed only under similar conditions. It will accordingly be gratifying and satisfactory to know that a scholarship called "the Roman scholarship," of the value of 1,500 dols., the holder of which will pursue his studies at the school, has this year been offered to be competed for by graduates of any of the architectural schools in this country, or by members of the Ecole des Beaux-Arts of two years' standing who are less than thirty years of age.

It is believed that the foundation of the school in Rome marks a distinct advance in the history of professional education in this country, and that it will result in the creation of a common standard of instruction in the different institutions whose work its chief aim is to continue.

THE ROYAL DUBLIN SOCIETY.

THE annual report of the Royal Dublin Society contains the following reference to the new lecture theatre:—

The Council have much pleasure in reporting that the building of the new lecture theatre is at length in progress. At the general meeting of the Society twelve months ago the Council were obliged to express their disappointment that so much valuable time was being lost, more than a year and a half having elapsed in negotiations. On April 17, 1894, some members of the Council had an interview with the Commissioners of Works and saw, for the first time, the detailed plans upon which tenders had been obtained. As a result of the conference a letter was received from the Commissioners, dated April 24, 1894, in which they stated that it had been found necessary, for the sake of economy, to make alterations in regard to materials to be supplied, but that otherwise the design of the proposed fabric would remain precisely as designed by Sir T. Deane & Son, with the following exceptions:—(1) The coal-cellar and boiler-house in the basement; (2) the sliding-stage and diagram-board; (3) spare or photographic room over offices; (4) the organ-loft; (5) the room over front colonnade. Items 1 and 4 the Council admitted to be additions to the original design, and they accordingly agreed to provide the sum of 483*l.* 2*s.* 8*d.*, which these additions were estimated to cost. The other items the Council regarded as essential parts of the original design, and they urged that they should be included in the contract. It then transpired that a serious difference of opinion existed about item No. 5—the room over the front colonnade. It was claimed by the Society that this room was shown on the plan attached to the agreement which the Commissioners had entered into with the Society for the building of the theatre, as one of the rooms to be provided for the Society. It was contended that the room could not be omitted without infringing the agreement, which provided that any modification of the plan attached to the agreement that might be found necessary should not "entail any diminution of the accommodation shown by the said plan." On the other hand, the Board of Works maintained that this room had no necessary connection with the requirements of a lecture theatre, and that it was intended solely as a substitute for the present unsightly wooden passage connecting Leinster House with the museum. They pointed out that the Science and Art Department had claimed the room for museum purposes. In this juncture the Council sent a deputation to London to place the Society's case before the Treasury. The decision subsequently arrived at by the Treasury was conveyed to the Society in a letter, dated May

26, 1894. This letter stated:—"Two courses are now open—(1) to proceed with the work, excluding entirely the room in question; (2) to carry out the work as tendered for, adding thereto the room over the portico, and also a room above it, having the same area, but with lower walls." The latter room their lordships proposed to place at the exclusive disposal of the Society. The Council were not disposed to assent to either of these proposals, and being fully convinced of the justice of the Society's claim to the room in question, they proposed that the point in dispute should be decided by arbitration. This proposition was declined, and it appeared for the moment that further attempts at a settlement of the question were useless. It was found, however, at an interview with the Commissioners of Works that a compromise was possible, and the Council embodied the conditions they were prepared to accept in the following resolutions:—"Resolved—That the Council assents to the possession of the first floor portico room being given to the Science and Art Department as a connection and as a means of communication between its offices in Leinster House and the Museum Buildings, it being, however, a condition that the room in question shall be built concurrently with the lecture theatre, and in accordance with the plans already agreed upon. That the Council accepts the alternative proposal No. 2 as set forth in the Board's letter of May 26 last, on the understanding that in carrying out the work as tendered for the following shall be included, and the cost defrayed by the Commissioners:—1. The coal-cellar and boiler-house, estimated cost 133*l.* 2. The sliding stage and diagram board, estimated cost 164*l.* 3. The second floor portico room. 4. In the laboratory rooms, a firm concrete floor on rolled steel joists, the concrete being covered with planking. That as regards the room known as the spare or photographic room, estimated to cost 177*l.*, the building of this room shall be carried out simultaneously with the construction of the theatre, the funds to meet the expense being provided for out of any excess beyond 5,000*l.* cash realised on sale of the 2½ per cent. stock, now standing in the names of the Commissioners and the Royal Dublin Society, the Society undertaking to make good any deficiency as between such excess and the said sum of 177*l.*" In a letter dated July 11, 1894, the Board informed the Society that the Treasury had sanctioned the execution of the work in accordance with the foregoing conditions, and that it would be pushed forward as expeditiously as possible. Shortly after the contractor had commenced operations the Council drew the attention of the Board to the importance of having a proper system for heating and ventilation decided upon from the outset, and submitted particulars of the conditions which, in the opinion of the Council, it was necessary to observe. This matter is now under consideration; no decision has yet been arrived at. The Council attach the utmost importance to the heating and ventilation of the new building, and they will do everything in their power to insure that in this respect the new theatre shall be as perfect as it can be made.

DISCOVERIES AT BATH.

IN his report to the Town Council on the excavations at the Roman baths in Bath, Major Davis states:—

In following the Roman wooden duct at the baths which has been previously described, the workmen have come across another Roman drain built of colossal stones, some of which are 7 feet long, the bottom of which is also paved with stone. In removing the soil several interesting antiquities have been discovered.

1. A bronzed barbed fish-hook of very delicate form about 1 inch in length.
2. A crystal belonging to a ring oval 7·16th of an inch long by 5·16 wide and 3·16 thick.
3. An Egyptian blue glass bead with a pattern in white.
4. A sardonyx with a figure on horseback apparently holding a large wreath, very spiritedly engraved. The stone is oval, nearly half an inch long by 3·8th inch wide and 3·32nds inch thick. Unfortunately this is a little chipped.
5. A chalcedony, a seated helmeted figure under a tree, and what appears to be a goat, oval, 5·16th inch long, by 9·16th inch in thickness, 3·32nds. This is of very rude work.
6. An amethyst, a nude figure in a biga driving very spirited horses, over 7·16th inch long, by 5·16th inch, and 3·16th thick. The other stones are all engraved on a table surface; but this is convex. There are two other mock stones, one the colour of an aqua marine, the other a sapphire. They appear to have been engraved originally, but too obliterated to decipher. Since writing the above I have found the following in the same drain:—
7. A bloodstone, a winged lion has the advantage of horns. I suppose I should be more correct in calling it a chimera oval, 7·10 by 6·16 and 3·32 inch thick.
8. A chalcedony, a very rude representation of an eagle

oval nearly 9-16 long by 7-16 wide and a trifle over 1-16 inch thick. We also found three coloured glass rings or beads.

Both seven and eight appear to be unfinished work, and if this is the case they may indicate that the smaller rooms of our baths were used as shops (Torbernæ), and that lapidary was one of the trades patronised by the bathers. The idea that such shops existed is further strengthened by the finding of a fish hook in the drain, as it could be easily accounted for if I may assume that a fishing tackle maker had also a shop at the baths.

Major Davis, according to the *Bath Argus*, pointed out that the intrinsic value of the antiquities amply compensated for the expense incurred in discovering them. Perhaps the Chairman had better keep them in his custody. They were found in the stone drain, which he hoped the committee would not object to his having washed. He had only just got about five or six feet into the duct, and had not discovered the outlet, but he had found a drain, of the existence of which he was previously unaware, leading into York Street.

Mr. Taylor, in moving a vote of thanks to Major Davis, said it would be a pity to stop him in the midst of his inquiries, everything which had turned up having proved of the greatest interest.

Alderman Commans seconded, and said he thought Major Davis should be allowed to proceed until he found the exit.

Alderman Freeman: The duct may have no exit.

Major Davis said it was worth while going on for the sake of finding more relics, which were generally most thickly collected in pits such as the Romans probably used as rubbish heaps.

Sir Jerome Murch thought they should know the expense before they began.

It was decided that the surveyor works should go on with his present investigations as to the duct.

Mr. Morris suggested that a winch or crane should be erected in order to save expense and labour in removing the debris as it was unearthed, and it was decided to carry out this proposal.

The Mayor proposed that the Council should be asked to vote a sum of money for the purpose of pursuing further investigations.

Alderman Freeman said Mr. Irving's collection had been lost sight of. Mr. Irving had considerable information as to the remains under the Pump Room of which they knew nothing. There was probably a portion of the old Temple of Minerva; what had been done was mere child's play compared to that.

Mr. Radway protested against any further steps being taken. If the committee proceeded they would be in for hundreds of pounds.

Mr. Oliver: Thousands.

Mr. Morris said that Messrs. Long's charges must not be confused with those incident on the other excavations. He had no objection to Major Davis going on as long as he found relics.

The mayor's proposal was then carried.

Specialties in Quantities.

SIR,—Re above, as per letter in yours of the 8th inst., may I, as one connected with a firm of cement manufacturers, ask you to insert a few lines which, from our present day experience of the far too low a price which cement is generally put on the market, seems to be the only remedy for the growing evil of "Cut prices, cut quality." We have always made it our business to manufacture a specialty, that is, an article superior in strength, durability and reliability to that usually put on the market. In former times we had far less difficulty in getting the public to pay a high enough price sufficient to induce us to strive at improving the quality of our manufacture, but now in these times of extra competition many of them say, "We would rather use your cement, knowing it as we do, but every shilling has to be looked at; and as we can buy a cheaper article good enough to meet the standard, we consequently cannot afford to use what choice would suggest but necessity debars." Public companies who do their own work buy the best materials, because result is everything and they have no competition. But in open tendering, unless the best articles are specified they are seldom used; consequently to induce all of us to improve our quality is for those who draw up the quantities to specify what their experience tells them is the best, or to allow extra portions of sand or ballast to those manufactures which are practically proved to be superior and

in the long run the cheapest material. None of us can spend increased money in improving quality unless it is recognised by our having the help of being specified, which prevents contractors tendering on any but the specified articles.

March 19, 1895.

GAMECOCK.

SIR,—In your issue of March 8 there is much of truth in the letter from "One in the Know." I as a salesman in a large merchant's business, with one of the largest and oldest connections, find the difficulty of selling an article considerably superior to that generally put on the market because it happens to cost some 10 per cent. more to manufacture it, and consequently its sale price is increased to that extent, which extra quality is the chief cause that brings it under the head of "specialties." Many customers, knowing its superiority, and fearing to lose a hard-earned reputation, use it, but grumble at its increased price; others, while admitting its superiority, decline to pay an extra price when they can get a substitute, which, while being a far less durable article, will pass muster at the low standard generally in force in the market. The too keenness in competition at the present time means much using of materials of the cheapest kind, which, below a certain point, must be made a sacrifice of quality, the result of which is the investor and subsequent owner, though possibly saving a trifle in cost of a building, pay too high in price for what is often not built with the best manufactured articles, and which in small speculation builders is called "jerrying." The remedy is this:—Specifiers in quantities must recognise manufacturers of proved superiority by definitely specifying them. The merchant builders would far rather sell the best class of building materials, but when "A1" class of goods are not specified, we can only sell at the price of inferior articles, which is what, at the present time, we are chiefly asked for.—Yours truly,

MERCHANT.

GENERAL.

Mr. A. Grainger Eejton has been appointed architect for the restoration of the Perth Municipal Buildings, lately destroyed by fire.

Mr. H. G. Hine, Vice-President of the Institute of Painters in Water-Colours, died on Saturday last at an advanced age.

An Anonymous Donor has sent a cheque for 5,000*l.* to the building fund of the new St. Peter's Church, Eastbourne. The Duke of Devonshire gave the site and 5,000*l.* towards the erection, but owing to the want of funds the committee had decided, until this gift came to hand, not to proceed with the erection of the chancel.

The Designs and Looms of the Royal Windsor Tapestry Works were sold on Monday by Messrs. Barber & Harding, this dispersal of the plant marking the extinction of a costly undertaking, which for a time promised to revive an ancient decorative art in England.

Mr. H. Montague Bates, hitherto assistant clerk to the City Commission of Sewers, was on Tuesday appointed principal clerk in place of Mr. Blake, resigned.

A Monumental Stone has been placed in Peterborough Cathedral, over the spot on the north side of the chancel where the remains of Queen Katherine of Arragon were buried. The cost has been defrayed by the "Katherines" of England, Scotland, Ireland, America and others. The inscription is as follows:—"Here lies the body of Katherine of Arragon, Queen of England, and first wife of Henry VIII., who died at Kimbolton Castle on the 8th day of January, 1535-6, aged forty-nine years."

Warehouses for the scenery of the Opera and Opera Comique, Paris, are about to be commenced at the fortifications. The contracts for the masonry, carpentry, ironwork and roofing are settled.

M. Puvis de Chavannes has received the distinction of Commander of the Order of Leopold from the King of the Belgians, as well as Sir J. E. Millais and Sir J. D. Linton.

The Students who are to compete for the Prix de Rome in architecture are M.M. Dusart, pupil of De André & Laloux; Duquesne, pupil of De Pascal; Bigot, pupil of De Laloux; Mercier, pupil of De Laloux; Patouillard, pupil of De Ginain; Pille, pupil of De Pascal; Garnier (Tony), pupil of De Blondel; Umbdenstock, pupil of Guadet & Paulin; Aubutin, pupil of De Pascal, and Lemaesquier, pupil of Laloux.

An Official Return shows that within the municipal limits of Venice there are 14,182 houses, inhabited by 31,419 families.

The Design by Messrs. Campbell Douglas & Morrison, of Glasgow, has been adopted for the new free library at Perth, which is estimated to cost about 9,998*l.*

The Royal Society of Water Colour Painters has, by the death of Mr. A. D. Fripp, lost a zealous secretary. He was born in 1822, and since 1846 has been a member of the Society.

The Architect.

THE WEEK.

WHEN the British Archaeological Association passed a resolution in connection with proposed excavations at Tara, in noticing the matter recently we took occasion to doubt the desirability of disturbing the remains of the dead. We are not surprised now to be informed that the action of the English Association does not commend itself to Irish archaeologists. Some of the better-informed members of the Council of the British Archaeological Association, endeavoured, but without much success, to dissuade the raiders from interfering with what might be allowed to remain in the hands of the Royal Irish Academy and the Royal Society of Antiquaries of Ireland, if it were necessary to carry out such a work. The latter Society visited Tara last summer and appointed a committee to report on the scientific investigation of the Tara and other mounds in County Meath. It has been ascertained by the local societies that, in making an estimate of the cost, a sum must be included sufficient to cover the expense of a special police force while the work is progressing. As matters stand at present, if the explorers were fortunate enough to avoid having proceedings taken against them in a criminal court, they might find themselves involved in a civil action. It is not likely the British Archaeological Association will do anything in the matter, and the feeling is against their interfering in explorations outside England, and more especially as great energy has been shown by the Royal Irish Society of Antiquaries in dealing with all those matters relating to the past in Ireland where there are no reverential feelings to be outraged by navvies with pickaxes and shovels. It would be wiser for the British Archaeological Association, if they must have Irish spoil, to set about a search in the curiosity shops of London for the famous harp "that once through Tara's halls the soul of music shed" rather than to make a raid on the graves.

In a generous spirit Mr. HINE undertook to give the Dublin Poor Law Guardians the benefit of his experience in judging the plans of the Portrane Asylum. But he has not received much gratitude. The report of the assessors on the competition seems to be rather severe on Mr. HINE, who was, strange to say, one of the three. It expresses regret that none of the competitors exhibited any experience of asylum planning. Now as the leading inspiration of two-thirds of the plans submitted was bodily "lifted" (and with commendable discretion) from Mr. HINE's own Claybury plans, the assertion is rather hard, although appearing in sorrow rather than in anger. The "predominant partners" in the determination, like the Progressives on the London County Council, have taken advantage of their tyrant majority in reporting regardless of what Mr. HINE may suffer. There seems to be general and well-grounded dissatisfaction that the Board of Control have not fulfilled their explicit printed conditions, which undertook to place three designs first, second and third in order of merit, but instead bracketed three as "equal," and finally, it is understood, has given the job to Mr. ASHLIN, who out-distanced other competitors by 40,000% in his estimate, and by acres in dispersing his buildings over the ground.

It is commonly said that money is cheap in the market, but people are by no means more eager than formerly to risk any in becoming sureties. At one time the becoming surety for a contractor was a sign of friendship between the parties, subsequently it suggested the relation of merchant and customer, finally it becomes a sort of insurance, and represents an outlay of money. Is it not time, therefore, that the lodgment of an adequate sum of money should be considered by those who enter into contracts for the execution of works by contractors as equivalent to an undertaking by men who thereby become sureties? But the deposit of money would be an innovation, and it may be

acute lawyers could discover that it was attended with risks. Otherwise we cannot understand why a committee of the Glasgow Corporation should on Monday have preferred persons to money. Messrs. MORRISON & MASON, the contractors for the excavation, masonry and brickwork at the Ruchill Hospital, offered to deposit 5,000% as security for the due fulfilment of the work. The acceptance of the proposal was moved and seconded. The Clerk, however, raised the objection that, in the event of a contractor becoming bankrupt, his creditors would have a claim upon the money. That opinion was disputed, on the ground that money assigned to a specific purpose could not be alienated. It might be possible in contract deeds to make an arrangement of that kind. When the voting took place it was found that twenty members were favourable to the innovation, while twenty-two wished to preserve the old system. The contractors will therefore have to pay a higher sum for security than they can obtain for their money.

It was hoped that on Tuesday there would be a decision about the extension or rebuilding of the Manchester Infirmary. The building occupies so prominent a position, it suggests the charitableness of the city, and on that account many wish to preserve it. But old hospitals are dangerous to patients, who should not be sacrificed to sentiment. On February 26 it was proposed by the board of management that two lateral extensions should be constructed. An amendment was handed in stating "that it is advisable that the increased accommodation required be provided by the gradual rebuilding of the infirmary on the present site, and that the board of management be requested to have plans prepared and submitted to a special meeting of trustees, to be held within three months from the present date." In order to give opportunity for all the trustees to consider the two projects, a poll was taken. It was announced on Tuesday that 442 trustees were in favour of gradual rebuilding and 154 for extension. The former course was therefore victorious, but three amendments to the amendment were proposed. One was—"That the plans prepared by Mr. BRIDGEN and Mr. HEATHCOTE, shown by the model in the room, and which were recommended in the annual report for adoption, whereby the required additional accommodation can be obtained by raising the roof an additional storey, are hereby approved by the trustees." But it was rejected by a large majority. The second amendment, to the effect that only such additions should be made as were necessary, was withdrawn. The third amendment, which was as follows—"That before proceeding further a committee, consisting of the members of the infirmary board, and an equal number of trustees who are not members of the board, be appointed to report on the best means to be adopted for increasing the accommodation afforded by the institution"—was adopted. After the long period already occupied in discussions, the result will not appear satisfactory, but it must be allowed the problem presents many difficulties.

THE Dean of Peterborough has made an appeal for aid towards the restoration of the west front of the cathedral. During the storm on Sunday last it suffered very severely. Four of the pinnacles have been injured or destroyed, and it is feared that many other parts of the façade have been seriously shaken. The full extent of the damage cannot be ascertained until Mr. J. L. PEARSON, R.A., has made his examination, but from a preliminary inspection which has been made by Mr. JOHN THOMPSON, the builder, it is manifest that a considerable expenditure is immediately necessary to secure the safety of the west front. The gables of the north and south transepts and part of the eastern chapel have been for some time pronounced by Mr. PEARSON to be in an unsafe condition, and the Dean has been endeavouring to raise the sum necessary for their repair. The interest attached to the cathedral is not confined to the people of the diocese. The preservation of the building should be a national concern, and we have no doubt the Dean will be gratified by a liberal response to his appeal.

THE PARIS EXHIBITION OF 1900.

IN this era of development it would be difficult to find a more convincing example of the principle than is presented by the buildings for international exhibitions. The idea which inspired them was undoubtedly derived from the French. It is true their exhibitions prior to 1851 were national rather than international, but they demonstrated that a large collection of industrial products in one place could become attractive. The French examples also suggested the advantage of having temporary buildings. When the project of an international exhibition in Hyde Park was devised, one of the early difficulties arose out of the apparent unfitness of the majority of the designs for the buildings. They were, if we might say so, too architectural. They did not suggest a transient undertaking. When PAXTON, who knew about the anxiety of the Commissioners to get hold of something bright, novel and removable, made a sketch on a piece of blotting-paper while he was supposed to be trying a culprit, by his happy thought he made the world his debtor. His building was really a glass case without any pretension to form. The semicircular part of the roof, the "blazing arch of lucid glass," which broke the monotony, was a suggestion by BARRY, who wished to save some elm trees. The plan was as simple as the elevation, and was only a very long and narrow parallelogram with two short transepts. Its success, however, has become legendary. To THACKERAY it was "a palace as for fairy prince, a rare pavilion, such as man saw never since mankind began." Twenty years afterwards it appeared to Sir DIGBY WYATT, who had seen all its successors, as an almost ideal building, which enabled single objects to be studied in detail, and yet allowed of grand pageants which could be enjoyed by large numbers of people.

In the French Exhibition of 1855, the temporary character was only partially adopted for the buildings. The Palais, which is still sound enough to be used for the Salon exhibitions, was a departure, as well as some of the pavilions which still exist. But all objects were not under one roof although the outlying parts were not distant. The exhibition of 1862 in London consisted of a series of contiguous buildings.

The plan of the Paris Exhibition of 1867 was an innovation, and undoubtedly one of the best that could be adopted for those who wished to study the products of the world. It might be described as a sort of ellipse with straight sides. The inner divisions corresponded with the exterior, and the intersecting routes enabled a visitor to study the objects of one country and in many cases objects of one class produced in different countries. The objection to the plan was that State ceremonies and other spectacular displays were impossible. The central space was laid out as a garden. We may grant, however, that the world is not so eager for ceremonial displays as in 1851. Business is now the inspiring principle in exhibitions. The exhibition of 1878 in Paris was evidence of the change, and the last exhibition of 1889 made more allowance for pleasure-seekers, inasmuch as there were great gardens and many outdoor attractions. There was, however, no part on which all eyes could centre, with the exception perhaps of a stage. But that part was so unsuitable for display that when the late Mons. CARNOT wished to welcome all the world to Paris he was compelled to take up a position in one of the galleries.

The conditions of exhibitions are greatly changed since 1851. The possibility of covering with one roof a space that would be equal to the requirements of the different departments is an impossibility. Engineering science has hardly the power to exceed what was done in the hall of machines in the Champ de Mars, which was about 370 feet in span. Separate buildings cannot be avoided. In 1889 it was found advantageous to make use of the Trocadéro building, although it was separated from the principal buildings of the exhibition by the Seine. We suppose it was found that the distance which had to be traversed did not cause much inconvenience, otherwise we could not expect that the scheme for the exhibition for 1900 should comprise so large a region and so many separate buildings.

The competition which was lately decided in Paris was merely one of ideas. All the premiated plans have been co-ordinated, after several weeks of labour, by M. BOUVARD,

with the assistance of some of the prizemen. From what has been deduced, it is now possible to obtain a notion of the exhibition that will inaugurate the coming century. In the first place, it will cover an extent of ground that is without precedent. The Champ de Mars and the Trocadéro will be used, but in addition a part of the Champs Elysées and the Esplanade of the Invalides. In other words, the Seine and a great deal of the open land on both its sides will be comprised within the boundaries. A new bridge across the river will unite the right and left divisions, and the roads which will be laid out will be arranged on lines that will allow pleasing views to be obtained.

Although crowds of people found their way in 1889 to the Champ de Mars, it is not the most attractive part of Paris. It is quite possible that if the forthcoming exhibition were confined to similar limits the success would not be renewed. For that reason we suppose the grand entrance of the exhibition will be in the Place de la Concorde. By that arrangement one of the favourite spots of Parisians and of all visitors to the city becomes, as it were, a key to the exhibition. On entering the visitor will find himself in an open space surrounded with statuary. This will lead him to several of the buildings which will be consecrated to fine art or to industrial art of the kind associated with Sevres. The Palais de l'Industrie, now used for the Salon exhibitions, will be supplanted by another of a more important character. If the bridge is crossed the visitor will find on the Esplanade of the Invalides more buildings which will be devoted to industrial art. Whether the arrangement is more logical to begin with the arts of the highest class instead of with materials may be left to theorists for discussion. One thing is certain, that the majority of visitors will be gratified by it, and France is suggested by the giving of prominence to what is beautiful.

The ordinary visitor is likely to be tempted, especially on fine days, to begin as soon as possible with the buildings which will line the river on both sides. Certainly they will be varied in character. Some will seem apposite, such as those which relate to the department of the marine in all its branches, and those relating to maritime and fluvial industries. But there will be also conservatories, kiosks, cafés, examples of buildings from foreign cities, and so on. Business and pleasure will be combined in what we may call the intermediate part of the exhibition, and a good many visitors will be likely to wish that the rest of the exhibition could be seen by deputy.

The importance of the objects that will be shown in the Champ de Mars cannot, however, be doubted; moreover, pleasure will not entirely be banished from the region. The Eiffel Tower will of course remain, but it will assume a more pleasing appearance, unless French ingenuity is less inventive than formerly. The hall of machines will be also conserved, but it will be rearranged, and at least a part of it will be utilised for public fêtes.

It is proposed to lay out the ground symmetrically. On each side there will be buildings of corresponding lengths, which will run nearly parallel with the river. As they will increase in length in proportion to their distance from the Seine, their character will be suggested at a glance to a visitor who stands near the Tower, and satisfactory perspectives can be enjoyed. The space between the buildings, which of course becomes widest as the Tower is approached, will be laid out in a variety of ways, fountains and lakes, which can be illuminated at night, being among the features. It is intended to have a separate palace for each of the great divisions of industry, and to assign to electricity the supreme position. By the close of the century who knows whether it may not be superseded by some other power? As a rule, each industry will have about one-half more space than was allotted to it in 1889.

The Trocadéro, or rather the grounds available in the neighbourhood of it, will be utilised for exhibitions of objects from the colonies. Here also we may expect to see the roving populations from east, west, north and south that are now inevitable with all exhibitions that claim to be international.

The task undertaken by M. BOUVARD has been most onerous. His plan appears to be satisfactory. It is not clear what will be the dominant part, but that is not always to be discovered beforehand. There is no doubt that in 1889 the Eiffel Tower, in spite of its demerits,

caught the fancy of the public: between now and 1900 it may be possible to discover something that will be a rival to it. But a still heavier task is before M. BOUVARD. It will be necessary for him in a couple of months to furnish an estimate of the cost of one of the most colossal undertakings that has been attempted since men began to build. The exhibition of 1851 cost 176,030*l.* 13*s.* 8*d.* The works proposed by M. BOUVARD will require, we suppose, an outlay of more than twenty times that sum. The French show in these matters a liberality which we can hardly understand in England. In 1867 they paid 22,983,820 frs. for their exhibition. In 1878 the amount rose to 55,390,000 frs., and in consequence they lost about 32,000,000 frs. The expenditure in 1889 was said to be 41,500,000 frs. It is considered by some speculators that double the last sum will be needed. It is an enormous outlay, but the receipts may correspond in amount. At all events, France is pledged to have an exhibition of an unprecedented kind in 1900, and that must be realised whatever may be the sacrifice.

GLASGOW ARCHÆOLOGICAL SOCIETY.

AT the last meeting of the Glasgow Archæological Society the chairman, Dr. David Murray, made fitting reference to the great loss which the Society had sustained by the death of their president, Mr. C. D. Donald. Mr. Donald, he said, had been cut off suddenly and in the midst of his days, just when his faculties had come to full maturity, and when reading and thought, experience and observation, were bearing fruit in a firm grasp of affairs and a deep insight into life and action. It was but four months since they welcomed him to the president's chair, but he had long been a member of the Society. Mr. Donald was not a specialist in any branch of archæology, but he was well acquainted with the trend of archæological science and had a thorough grip of the principles upon which antiquarian investigation must proceed. While a rapid and vigorous worker himself, he had the art of getting others to work likewise, and many a paper the Society owed to his good-humoured and persuasive solicitation. Mr. Donald was the founder and the heart and soul of the Regality Club. He was the author of many of its papers, and all the others were written on his suggestion. Mr. Donald had excellent opportunities for learning all that was to be learned by tradition of the leaders of city life in the last three or four generations; but he never relied upon tradition if it was possible to substantiate a statement by documentary evidence, and many an hour he spent in investigating complicated titles and obscure records in order to verify a fact. The result was a series of graphic and accurate accounts of the Glasgow of last century. Mr. Donald was as active in the field as in the study. Those who accompanied him on Saturday afternoon rambles, or on longer walks in summer-time, would remember him as the cheeriest of companions. It was perhaps only after a while that they realised how much they had learned from him, and how his quiet enthusiasm and crisp way of putting things had aroused their interest in archæology. Had he lived he would have proved a most valuable head to the Society. He could not have failed to lift them up and impart some of the fresh and vigorous life which he himself enjoyed to the full. As it was, they could only mourn their loss. He therefore moved that they place upon record their sense of the great loss which the Society had sustained by the death of Mr. Donald; their appreciation of his services to the Society, and their sympathy with his family in their bereavement.

Mr. J. Dalrymple Duncan, hon. secretary, in seconding the motion, referred to Mr. Donald's varied and valuable services to the Society. The late President, he said, possessed all the qualifications of an archæologist—wide reading, calm judgment, untiring energy and the gift of a fresh and attractive literary style. Unfortunately the engrossing demands of his business prevented him from being able to give to the subject the time which in other circumstances he would have devoted to it. By his death Glasgow had sustained a great loss, a blank had been made in the ranks of the profession which he adorned and a heavy blow had fallen on the Society.

Dr. J. O. Mitchell also spoke in appropriate and feeling terms of the loss they had sustained by the death of Mr. Donald.

The motion was adopted.

Mr. George Neilson read a paper on "Caudatus Anglicus: a curious Mediæval Slander." Mr. Neilson dealt with the origin and history of the term "Caudatus Anglicus" applied to Englishmen. It was shown to have been in use from the end of the twelfth century, invariably applied to Englishmen, and in a great mass of cases in conjunction with

sarcastic references to the possession of tails. Divergent theories had been propounded to explain this remarkable middle-age belief. The two most important were, first, an etymological explanation which accounted for *caudatus* as signifying a coward and connected with a tail between the legs. The other explanation was that given by Mediæval chroniclers and ancient legend. These latter authorities said that when St. Augustine came into England the inhabitants of a southern county mocked him by affixing fish-tails to his garments, and that in divine revenge the inhabitants of the district ever afterwards carried tails. Many citations were given showing the use to which this epithet was put, being frequently applied by Frenchmen and by Scotchmen to Englishmen, and forming a somewhat spicy part in the epigrammatic quarrels between representatives of these antagonistic nations. Mr. Neilson's opinion was that the etymological explanation was inadequate, and that the term was the evidence of a widely-existing belief of early ages that in certain parts of England men had been punished by the infliction of tails.

THE PORTRANE ASYLUM COMPETITION.

THE design of Mr. G. C. Ashlin, R.H.A., has been selected for the new asylum which is to be erected at Portrane, near Dublin. An article on the subject appears in the *Irish Times*. It runs as follows:—

In order to complete the later history of the competition, and elucidate its announced ending, we must go back to the report of the committee of selection. They were appointed to take three out of the designs sent in, and to "place them in the order of merit." What they said was this:—"With reference to the designs we have very carefully examined the twelve sets of drawings submitted, and while we consider that they reflect great credit on the authors, showing that much time and attention have been bestowed on their preparation, we regret to say there is evidence of but little experience in asylum planning, and we have great difficulty in selecting three designs which adequately fulfil the conditions for a well-arranged asylum." Nevertheless, they did thus name the three following designs, viz. "Luna," "Mens Sana" and "Aspect." "But," they added, "we cannot recommend any one of them for adoption without very considerable alteration, and therefore we propose to bracket the three designs together, leaving the final selection in your hands." Thus the Board of Control had three designs in the largest sense of equal merit, though in some particulars all alike were defective. They have now taken a course which can hardly be pronounced to be fair altogether to the two rejected designs in selecting the most expensive of the three, giving to its author the liberty of amending it, and of reducing the outlay—it is said by 40,000*l.*—a liberty substantially of re-tendering which in no shape has been conceded to Mr. Rawson Carroll or Mr. Kaye-Parry, though their claims stood equal with that of Mr. Ashlin. The decision has thus been conveyed:—"The Board of Control have given the selection their most careful consideration, and have decided on accepting the plans furnished under the motto 'Aspect.' As the three designs referred to were bracketed by the assessors, the Board have decided to divide the amount provided for premiums, 225*l.*, into three equal sums of 75*l.*, and have ordered payment of that amount to be made." The case consequently stands thus:—That of three equal plans the most costly has been selected. Secondly, the least attractive plan as to expenditure is to be, as we have heard, cut down to somewhat near the level of the plans that competed with it. Thus a merit is communicated to it by a special concession which before it did not possess. But no privilege corresponding in any way to this was offered to the other architects, enabling them to alter their designs in an iota. When, accordingly, the Board came finally to make a choice they appear to have done so as between two of the "equal three" plans unchanged and unmodified and one other altered, we are in no position to estimate to what extent, though we must infer that it is considerable, from the reported amount of the reduction in cost. Whether any more useful or satisfactory arrangement than this could have been made for a combined service we cannot suggest; but those who presented the designs that are now rejected have, we feel, reason to complain that any privilege of modification should have been given from which they were excluded. The Board, many will think, when they determined to allow an architect to amend should have gone the full length of permitting the three equal architects to offer their plans afresh, with changes in them within certain limits not affecting their principle or the original conditions. Those concerned in the paying part of the matter would like to know what the Portrane Asylum is really to involve in the way of outlay, and whether the "Aspect" plan is, as now is stated, to be lessened to 200,000*l.*, a sum beneath that of the two other plans which in its original form it so much overtopped.

THE HALLUM BRASS, CONSTANCE CATHEDRAL.

AT the foot of the steps leading up to the high altar in the cathedral of Constance there is a monument particularly interesting to the English, on account of its connection with the history of their country.

It consists of engraved brass plates let into an oblong-square stone slab, about 9 feet by 5 feet in dimension, and represents the effigy of a bishop in the costume of the fifteenth century standing in an arched niche, which terminates upwards in a crocketed canopy, having on each side of it an escutcheon.

That on the dexter side contains the royal arms of the Plantagenets—quarterly, France and England, surrounded with the Garter of the Order of St. George and its device, "Honi soit qui mal y pense." The other, on the sinister side, probably contained (for the metal within the border of it has been removed) the private arms of the bishop, impaled with those of his see, and is surrounded by a scroll, in which appears in Gothic characters the words, "Misericordias Domini in eternum cantabo." At the sides of the niche are two pillars ornamented with Gothic panels, in each of which is the figure of an angel, and the whole is surrounded by a square border (separated from the other part of the monument by an intervening space of stone), which exhibits at each corner an ornament, in the centre of which is a figure, much defaced, but which seems to have been the representation of a dove, with a halo round its head, bearing a scroll, and probably intended to signify the Gospel proceeding from the Holy Ghost. Such a figure can

be clearly made out on the ornament at the bottom left-hand corner of the border, and it seems as if the other figures were merely varieties of that which has been particularised, and are the usual emblems of the four Evangelists.

The epitaph which appears on the border is in letters of a different character to those around the escutcheons. It sets forth the qualities of the deceased and the year of his death in the following quaint manner:—

✠ Subiacet hic stratus Robert Hallum vocitatus : ✠ Quondam p̄latus Sax sub honore creatus Hic decretoꝝ doctor pacis q̄ creator : Nobilis angloꝝ Regis fuit ambaciator : ✠ festu cuthberti septembris mense vigeat : ✠ In quo Roḡti mortem Constantia flebat : Anno Miffeno tricent octuageno : Sex cū ter deno cū x̄po uiuat ameno. ✠

The day of the bishop's death then appears to be the feast of St. Cuthbert, that is, September 4, 1416, for "Anno milleno tricent et octuageno" brings us to 1380, to which add six and thrice ten, "Sex cum ter deno," and the product will be 1416. It may be here remarked that the word "Christo" in the original inscription is contracted and expressed by an equivalent for the Greek characters ΧΡΟ, that is to say a Gothic α for the Greek χ (χ), a ρ for the ρ (ρ), and an \omicron for the \omicron (\omicron). Over the head of the effigy, in the quatrefoil of the canopy, is a rose in the centre, around which are the letters R. O. B. S., which may have been intended to denote the four principal letters in the bishop's baptismal name—Robertus. On the upper part of his dress, on the collar of the chasuble, there are two Gothic letters which look like A. V.

A notice of Bishop Hallum's death is contained in an old printed book dated 1483, and written in German, by Ulrich von Keichenthal, under the title of "Consilium von Costnitz." The translation is as follows:—

"On the fourth day of the first Harvest month, happened a Tuesday during which, VIII hours after midday, towards the night, there died the highly worthy Prince Bishop Robert of Salisbury from England, in the fortress Gotlieben; and on the morrow about vesper time there they conducted him to Constance, and they bore him with two golden cloths into the Minster, and thither went all Cardinals, Patriarchs, Archbishops, Bishops—our Lord the King—all spiritual and temporal Princes, prelates and priests, and with them a great crowd, by [the light of] LXXX of the largest-sized burning tapers—which poor old men bore—and they sung him a Vigil, and he was buried in the choir with the other Bishops; and they had for him there no offering."

According to the report of the sacristan at the cathedral of Constance, grounded on generally-believed tradition, the brass part of Bishop Hallum's monument was manufactured in England, and sent from thence to cover his remains. If this indeed be true it is an interesting fact, for it affords a presumption that in the early part of the fifteenth century our brass-engravers were reputed to be superior to those of the Rhenish cities, where the thing might have been executed without incurring the charge of transport and the risk of damage which must have attended any shipment from England. Certainly, the art of inscribing on brass does not appear to have been cultivated for this purpose so much in Western Germany as with us. There are effigies cast in brass and plated with it to be found, and we are informed that most of these are believed to have been executed at Nuremberg, where brass-founding is said to have been cultivated with success and at an early period. But in the many churches on and about the shores of the Rhine such a thing as an engraved plate monument of the early part of the fifteenth century is not to be seen. Perhaps the form of the escutcheons over the head of the bishop's effigy may be adduced as very slight evidence of English workmanship, for that form was prevalent in England in the year 1416, at which period the Germans had begun to adopt another, somewhat different, in depicting heraldic achievements. The garter and garter-like scroll, too, which surround the escutcheons, are peculiar to England. These little traits, although they do not amount to conclusive proof, give nevertheless an air of probability to the tradition. Indeed, no reason for disbelieving it can be founded on the general appearance of the monument. The inscription on its border was probably executed in Germany, for the letters of which it consists are very different to those round the escutcheons, on the collar and over the head of the effigy, and they resemble at the same time those which one often sees in Germany on gravestones of a contemporary date. Why the royal arms should appear on the monument in question is not known, unless it were to show that the bishop, when he died, was the king's representative.

Mr. Benajah W. Adkin, F.S.I., of 14 Queen Street, Chapside, E.C., has opened a branch office at No. 493 New Cross Road, Deptford, S.E., for the convenience and extension of his practice in the S.E. district.

THE RECORD OFFICE.

AS the new buildings of the Record Office, on the site of the Rolls Chambers, are approaching completion, we give a view of the original design, which was prepared by the late Sir J. Pennethorne. It will be observed that some parts differ from what is to be seen in Fetter Lane and Chancery Lane, especially the towers.

TESSERÆ.

Architecture and Painting.

SOME painters, instead of making architectural buildings serve as an ornament to their landscapes, completely spoil their compositions by great abuse of resources which it affords. Amongst these may be mentioned Marco Ricci, Lingelbach and sometimes Pannini. They availed themselves of their sojourn in Rome to copy the numerous monuments of various periods which there abound. This they did, however, without taste and discernment, and in their pictures they introduced promiscuously, and in the greatest confusion, monuments of different periods, of different styles of architecture, indeed of the most opposite character, accumulating these incongruous elements with a confused profusion of which Rome itself does not afford an example. In some instances they rendered this heterogeneous assemblage more ludicrous by intermingling figures of different dates and costumes with the ruins. Modern landscape-painters have devoted themselves more exclusively to nature herself, and have availed themselves generally in a less degree of such means of embellishment as architectural buildings afford. However, the French marine artist of the last century, Joseph Vernet, introduced architectural buildings, especially lighthouses, bridges and aqueducts, with great taste and effect, and his English contemporary, Wilson, realised corresponding advantages by the ruins of such monuments. Turner, when not led by the fascinations of colour to neglect the resources of ornamental form, availed himself most advantageously of the decorative beauty of architecture in his landscapes, as may be seen by the grace and elegance which his picture representing *The Building of Carthage* derives from its architectural monuments. John Martin so completely commanded the resources of architecture that he thereby imparted a character of combined splendour and vastness to his compositions. In some of his pictures ancient cities surprise the observer by their extent, their remarkable situation, and the originality of the buildings. In others, as in *The Feast of Belshazzar*, it is the magnitude of the palaces and other edifices which causes admiration. In these subjects a style of architecture has been adopted which, though to some extent ideal, at least carries the mind at once to the time and the place of the event recorded, an attempt which had not been made by the landscape-painters of olden times, and which,

although till lately quite new in this branch of art, Martin carried out with the most complete success.

Caprice in Design.

It is very common for people to set down at once for caprice whatever deviates from general rule and usual method, thereby perplexing that ordinary and petty criticism which has no other standard of judging than established routine precepts, interpreting them, moreover, to the very letter. Such criticism is unable to discriminate between what is mere caprice and what is not, wide as is the difference between them. The capricious is that for which no satisfactory reason can be assigned by the author of it, but however contrary it may be to usual practice, that is not caprice which is done with deliberate intention and well-studied aim at effects previously untried. And if to do well merely according to precedent be meritorious, much more must it be to do so and at the same time go beyond actual precedent, creating what in its turn will be recognised as valid precedent and authority. It is proper enough to be perfectly well acquainted with precedent, but to be tied down to it, to be made a slave to it, is ill. Those who are incapable of thinking for themselves take refuge in precedent, and make it their stronghold, since it enables them to assume a tone of authority, and to decide dogmatically without any trouble of thinking. Careful observance of rules will enable anyone to avoid positive faults, but between them and positive merits there is an immeasurable distance, one which defies calculation. In art it is very possible to be at once faultless and valueless, without any specific fault, but also without any interest or any charm—in a word, to be altogether humdrum. Perhaps it is rather unfortunate than not for architecture that a great deal of humdrum is of necessity tolerated in it; however worthless or unworthy they may be as productions of architecture, buildings may as buildings completely answer the purpose for which they are erected. Besides which they must when once erected remain indefinitely to the discredit of the art and the corruption of public taste. Humdrum poetry becomes serviceable as waste paper; humdrum pictures find their way into lumber-rooms and garrets, but buildings of the same or even worse quality cannot be so got rid of or put out of sight; otherwise a good many that might be mentioned would now disappear.

Decay of Granite.

The decomposition of granites takes place from the action of the atmosphere upon their constituent particles. "The quartz is almost pure silicious earth in a crystalline form. The felspar and mica are very compounded substances; both contain silica, alumina and oxide of iron. In the felspar there is usually lime and potassa; in the mica, lime and magnesia. When a granitic rock of this kind has been long exposed to the influence of air and water, the lime and the potassa contained in its constituent parts are acted upon by water and

carbonic acid; and the oxide of iron, which is almost always in its least oxidised state, or in that of the protoxide, tends to combine with more oxygen; the consequence is that the felspar decomposes, and likewise the mica, but the first the more rapidly." Such are the words in which Sir H. Davy describes the mode of decomposition of granites, and they may be taken to express the present state of science so far as the granites usually employed in England are concerned. But there appear to be different conditions in the combinations of the bases of felspar which give rise to some apparent anomalies. Thus the Egyptian porphyries, which contain a notable excess of rose-coloured felspar, resist the influence of the atmosphere in an extraordinary manner. Possibly this may be accounted for by the closeness of the grain (so to speak), which would to a certain extent prevent atmospheric moisture from communicating with anything beyond the immediate surface; or the more simple character of some of these porphyritic rocks may be favourable to their preservation; whereas the different rates of expansion of the ingredients must have a material mechanical influence in disintegrating rocks when they exist in considerable numbers. The difference between the rapid rate of decomposition of the porphyritic granites of Spain, Brittany and Cornwall, and that of the Egyptian specimens, appears to justify the inference that the cause last suggested has great influence upon their durability. The former are, in fact, composed of a greater number of ingredients than the latter, in which both mica and hornblende are wanting.

Colour in Architecture.

The subtle and delicate properties of form are truly worthy of occupying the mind of the artist, but there is no æsthetic reason why they should exclusively demand his allegiance. In later times the architect and the sculptor have limited themselves to the speciality of form apart from other properties, and yet on no valid ground, not even on the ground of precedent. It cannot now be denied that in all other ages than the last two or three centuries architects and sculptors have dealt largely with colour as well as with form, and have not thereby felt themselves degraded. Painters vary in their appreciation and application of the properties of form, yet no one thinks the worse of Michel Angelo or Raphael because he painted as well as drew cartoons. There is not one argument, indeed, for the exclusion of colour from architecture and sculpture which does not equally apply to painting. There is an enjoyment derivable from the properties of colour apart from form, which in its abstractedness is as pure as that derivable from the properties of form. The restriction of the practice of art to the latter has nevertheless no better basis than a vague, mystical notion, which seizes the more readily on some minds in proportion to its want of consistency and definedness. If purity of form is enhanced by being enjoyed alone and by being exhibited isolatedly, then an outline cartoon must be the height of pure art; and it may be submitted to the purists whether the play of light and shade which, both in architecture and sculpture, contribute so highly to effect, do not, like colour, impair the pure enjoyment of abstracted form. The more catholic the appreciation of the beauties of nature and of the resources of art the higher aimed will be the exertions of the artist, and it is equally honourable to him to work with slight materials or with small material. How anomalous is that law which would restrict an artist to marble and stone, and those only of one colour, and who require that his structures shall be of the greatest proportions and of the most durable materials, and yet will assign the honours of immortality to the designer of an altar-piece, nay, even of a cabinet picture. After all, there are more painters known to the world than there are sculptors, perhaps as many sculptors as there are architects whose names are in the mouths of the many.

Iron Manufacture in England.

The principal ancient seats of the iron manufacture in this country appear to have been in Sussex and the Forest of Dean, or Arden, as it was then called. It is known that ironworks existed in that part of Gloucestershire in 1238, because there exists among the patent rolls of Henry III. of that date one entitled "De forgeis levandis in foresta de Dean." Remains of ancient iron furnaces have also been found in Lancashire, Staffordshire and Yorkshire. The ironworks in the Monmouthshire hills now extend about twenty miles, and mineral property here has risen from 5s. an acre surface-rent to 1,500s., or more, underground. In the vale of Taff, before the seventeenth century, rude attempts were made to smelt iron ore; the bellows was worked by a water-wheel, and charcoal used instead of coke. Merthyr, the "iron capital" of the district, is scarcely a century old. Here, at the Cyfarthfa works, are employed upwards of 4,000 men, including colliers, and the strata of coal lie parallel with veins of argillaceous iron ore. This is the great seat of the bar-iron manufacture for railways. The chief ironworks of Sussex were in the Wealden strata, whence the iron ore was extracted from the argillaceous beds, and was smelted with charcoal made from the abundance of

wood. At Buxted, near Lindfield, iron ordnance were made three centuries since. Up to 1720 Sussex was the principal seat of the iron manufacture in England; the last furnace, at Ashburnham, was blown out in 1827. Kent was alike noted for its iron, and the last great work of its furnaces was the noble balustrades and gates which surround St. Paul's Cathedral, London; they were cast at Gloucester Furnace, Lambeth, and cost upwards of 11,202s. In the Middle Ages, and down even to a late date, while Dudley and Wolverhampton were obscure names, the forges of Kent and Sussex were all aglow with smelting and hammering the iron which the soil still yields, although it is not worth the while of anyone to work it. The discovery of the coal-fields of Wales and Staffordshire gave the Kent and Sussex furnaces their death-blow, leaving the country dotted with forge and furnace farms, and deep-holes, now filled with tangled underwood, from which the ore was brought. Kent and Sussex have no coal, and the iron manufacture left these counties when smelting with coal or coke began to supersede smelting with charcoal.

Caen Stone in Caen.

The lofty pinnacles and spires of Caen, and the solid high square towers which rise up in the clouds, defying the fury of the elements, for many years exposed to storms, hail, rain, snow and frost, acted upon by all the alternations of heat and cold, wet and dry, present a sharpness of arris and smoothness of surface, as seen from below, that prove a considerable degree of hardness in the stone of which they are constructed. Less reliance can be placed upon the indications on the parts within reach, for exposed as they have been to the Vandal wantonness of the revolutionary frenzy of destruction, and the Calvinistic zeal of misguided religious feelings, there are many of the lower parts broken away and considerably worn. But the attenuated and refined details of some Renaissance finials, pinnacles and flying buttresses in the lady chapels and apsidal altar-ends of the churches of St. Pierre and St. Sauveur and St. Sauveur-le-Marché of the beginning of the sixteenth century, more minutely enriched and elaborately carved and subdivided than even the most refined details of the flamboyant parts near them, are as fresh and sharp as if executed within the last fifty years. Time and weather have not had on the monuments of Caen the same corroding hideous influence as on the edifices of Chester, Coventry or Oxford. The graceful spire of St. Pierre, the summit of which is 250 feet above the market-place, and itself more than 100 feet high, does not appear to be thicker than 9 inches in the lower part, and is reduced, it is said, to 4 inches thick at top. The immense weight and exposed situation do not seem to have affected it in the least degree; and it may be quoted, if not for size, at all events for its grace, daring construction and state of preservation, after nearly six hundred years' trial, with its sister spire of Salisbury erected at the same period.

Influence of Contemporary Art on Students.

The minds of students are much more impressed, in the commencement of their studies, by the production of their contemporaries than by the works of the old masters, and these early impressions are never wholly eradicated through the longest life. There may be seeming exceptions to this, but there are very few real ones. That contemporary art is the first to impress us may be advantageous or otherwise, according to circumstances. Its advantages need not be dwelt upon, as such influence stands in no need of recommendation; but it may be useful to point out some of the dangers of what is certainly a habit with students resorting to annual exhibitions as a school. In an assemblage of the accidental productions of a year, and with which it is necessary to cover every inch of wall, there must of necessity be a great preponderance of the indifferent and even much of what is positively bad, and inexperienced eyes cannot dwell often and long on this without injury. The student is apt to thank his stars that he can do better than much that he sees, and contents himself with respectable mediocrity; and the more so as it is found that mediocrity, managed with ordinary tact, may secure patronage and even fortune, while unworlthy genius is often neglected. There are no topics more frequently dwelt on by writers and talkers than the faults of the age, and yet nothing is so difficult to understand. But to the student it is of the last importance that he should see clearly what are the besetting sins of the school to which he belongs. These, it is very true, are to be seen in their fullest luxuriance in annual exhibitions; but there is danger to the student, if he resort frequently to them for instruction, that he may become hopelessly blind to the mannerism of the day.

Single Style Zealots.

Those who admire one style of architecture are apt to be not merely indifferent to, but intolerant of every other. The lover of pure Greek architecture sees only the corruption of it in the Roman style, and of this latter, the degradation in the Italian. His standard of excellence is the Parthenon, and by that

standard he tries everything else, no matter how different may be the principles upon which it is constituted. He would have Greek-Doric temples spring up everywhere throughout the length and breadth of Europe and of America also. He is willing to extend some degree of favour to Ionic, that being at all events Grecian; but Corinthian is Roman, and shows a sad falling off from the manly simplicity of the earlier style. On the other hand, the lover of Roman and Italian design is equally strong both in his liking and his antipathy, holding Greek architecture to be frigidly severe and monotonous, exceedingly *borné* withal; and Gothic, together with all other Mediæval styles, to exhibit only the barbarous conceits of the Dark Ages—to be utterly devoid of "proportion," lawless, extravagant and irreducible to "rules." Such at least used to be the case, for at the present day such sweeping condemnation and insolent contempt of Mediæval architecture cannot be expressed with impunity. Gothic admirers and devotees repay with compound interest the insults and indignities which it formerly received from the Italian school and its followers. Opposite as they are in their tastes, all these parties are alike in one respect, they being all alike one-sided, prejudiced and intolerant in their antipathies, and cheating themselves out of much varied enjoyment by limiting the sphere of it to the compass of a single style of the art, instead of sympathising with the beautiful and intrinsically æsthetic in architecture, whatever may be the particular form under which it presents itself or the name to which it answers.

Blake, Barry and Terburgh.

Few men had more imagination than the amiable visionary Blake. No mind could be loftier in its aspirations than his—no heart more pure. He conversed daily with angels—he wrote poetry that Charles Lamb called glorious and Coleridge quoted by heart; and, so far, he had taste as well as imagination—and taste also purified by his imagination. But his pictures, though the subjects are sublime, are too fantastic to be looked at with any seriousness; for by a singular perversity of judgment he was led to associate sinfulness with the pleasure of the eye, and he spoke of being haunted by demons in the shapes of Titian, of Correggio, of Rubens and of Rembrandt, tempting him to commit light and shadow and to be guilty of colouring. Blake was mad, but this does not affect the argument, for madness is but an unbalanced mind, and the power he wanted was judgment—the better part of taste. Blake was but an extreme specimen of what is always more or less the result of the undue predominance of the imagination—and which as far as it throws off the control of judgment produces what may be called the fanaticism of art. Barry may be quoted as another, though a less extreme, instance of an extraordinary man devoting himself to a great object, and wilfully rejecting much assistance of the highest value. He spoke of the Dutch and Flemish painters, including Rembrandt and Rubens, as out of the pale of his church. And what is the result? He expended six years of thought and labour in the production of a series of pictures of high moral aim—but so deficient in the attributes of art that, though they may be acknowledged as the productions of genius, no power of reasoning will ever persuade the world to admire them. To Blake and Barry we may oppose, by way of contrast, Terburgh, as a painter of the least possible imagination, and whose works exhibit no remarkable degree of purity of mind. We must deduct, therefore, from his taste, all by which imagination and fine feelings might have exalted it. His subjects have rarely anything to interest, and we may be thankful when they have nothing in them to disgust; for he often descended to incidents of the most repulsive kind—a well-dressed woman, for example, tipping by herself, and in the act of draining a long Flemish glass, while she holds a stone bottle on her lap. Yet such subjects, and others little better, from his hands, are made gems of art by the exquisite taste of the colour, execution and light and shade with which they are recommended to the eye; and Terburgh ranks with great painters and is of a class from which Reynolds did not disdain to learn, and Raphael would not, could he have seen its productions; while the works of Blake can scarcely be said to belong to the art, and those of Barry, from their lamentable deficiency in all that can satisfy the eye, must take a rank far below the productions of the painters he most despised of the Dutch and Flemish schools.

Rosewood.

In seeking for wood of a fine figure special attention is to be paid to the appearance of the annular rings, as seen in the ends of the planks. When the concentric circles of red and black are found regular, or only slightly irregular, much show or figure is not to be expected. But when, on the contrary, they are found in waving and tortuous lines, a good figure is certain to be found. Another indication of fine figure is the plank being marked by knobby protuberances, which, when pierced, are found of a light colour. These, when intersected by the straight line of the veneer saw, produce an abrupt dash

of light, which contrasts very agreeably with the sober aspect of the general surface; and, therefore, planks having these knobs and other indications of figure should be carefully selected for veneers, while the plainer pieces are reserved for chair wood, couch-feet and scrolls, table-pillars and claws, and solid work generally. In cutting up veneer planks regard must be had to the form of the concentric circles in order to bring out the best figure which the plank is capable of exhibiting; and this object will be best secured by making the saw-draughts run as nearly as possible parallel to the circles. In drying rosewood, it is of importance to take care that it is neither exposed unsheltered to the rays of the sun nor suddenly to artificial heat, for either will have the effect of producing cracks, which, even although they close, cannot be concealed in the finished work. To make good furniture of this wood it is especially necessary that it be gradually and thoroughly seasoned, otherwise it is sure to betray the neglect afterwards. Another peculiarity of rosewood is, that much of it is very porous, and that the pores are elongated on the surface in a way that renders it difficult to produce a good solid body of polish on it. To remedy this, various plans have been tried. Size of various kinds has been employed to fill in the pores, but although well papered off, it furnishes a very harsh and ungenial surface to polish upon, and shrinks below the surface afterwards. Blackened bees'-wax has been rubbed in and then cleaned off, but this has the effect of preventing the polish from getting properly rivetted in the wood, and causes it, when the article is in use, to peel off on the least friction. The best remedy yet discovered is, after the surface has been finished by the cabinet-maker, to rub it carefully in with plaster of Paris, coloured with rose-pink, which, after being set, is to be carefully papered off. This does not shrink like the size, and has the effect of preventing the oil used with the French polish from finding a hiding-place in the pores, whence it afterwards exudes on exposure to the air, and eats off the polish like rust on a metallic surface. The dull brown colour of a large portion of rosewood has led to a variety of experiments to improve its appearance. Some have tried the dyeing of it with successive coatings of an infusion of logwood, but the effect is so unsatisfactory as not to repay the trouble. Others have used a strong solution of gum-dragon or dragon's-blood as it is commonly termed. This produces a very enlivening effect in superinducing a rich purple hue on the dull brown of the wood, but it always presents the appearance of a thick coloured or painted medium being interposed between the spectator and the wood. It is preferable to make use of a vegetable colouring, such as the extract of camwood, or other dyewood of the required tint, which in solution with spirits of wine, produces the desired change on the colour of the wood without suggesting the idea of its being painted.

Repousse.

A sheet or disc of metal having been selected, the artist sketches his design on the reverse side to that which is intended to be the finished work. He proceeds to raise the various projections by a series of punches, &c. When he has obtained the necessary convexities which he thinks will give sufficient relief to the subject and will look well, he fills the back of the work up with a mixture of pitch, rosin and sand, and attaches it to his chasing block or ball. He then works on the convex or right side with his chasing tools, with these adding the details of features, drapery and foliage. Any roughness is removed by means of rifflers; the work is then polished and thereafter burnished, gilt or parcel gilt. In this class of art the Italian gold and silversmiths of the fifteenth and sixteenth centuries were adepts. The art was revived in France in 1838, and has ever since been practised with success. In our own country Pugin, in his efforts to revive and improve the character, taste and style of ecclesiastical metal-work, introduced anew the art of beating up.

Motion in Painting.

In its highest flight art can only suggest motion. Those artists who try to represent it are guilty of an artistic solecism. They can, however, render it as commencing or finished, the threatening gesture, but not the descending blow; the intended, but not the actual movement; the effects, but not the action itself; a fallen stone, with the consequent injury, but not a falling stone. Such representations violate good taste, because they break natural laws by making immovable, as must result in art, a thing in motion. Consequently we perceive a painted and sculptured falsehood. This affects good taste as painfully as a lie does the moral man. But we may legitimately suggest motion, as in running water by its ripples, a wind by the direction given to all flexible objects on which it operates, and in animated nature by the natural position which hints at the coming or completed action. It would never do in representing a man walking to leave one foot suspended in the air; yet we continually see artists of repute, as the world judges, guilty of infractions of the laws of art as gross as the above example.

NOTES AND COMMENTS

THE report of the Sussex Archaeological Society announces that the year has been prosperous. It also mentioned that on October 10 a visit was paid by the members of the committee and a number of subscribers to Hastings Castle, when the dungeons were inspected and described. The museum was also examined, and the visit was most interesting and instructive. In October last a portion of the stone corbelling supporting the south-west tower of the barbican suddenly gave way, and upon an examination being made it was found necessary to shore up the tower and close the building to the public. The owners of the castle had, the committee understood, been advised that a large portion of the tower would have to be taken down and rebuilt. This unfortunate accident not only must of necessity somewhat impair an historic building, which will always be of special interest to the members of the Sussex Archaeological Society, but has already, and must for some time yet, cause a serious falling off in the number of visitors to the castle. As the Sussex Archaeological Society was founded in 1846, its jubilee will be in 1896, and the committee would be glad of suggestions as to the best way of celebrating it, and also promises of help in carrying out the commemoration in a manner befitting so memorable an event in the Society's history. The annual summer meeting of the members will be held about the end of July in Eastbourne.

THE names of the townlands in Ireland are evidence that the country was at one time thickly planted. But trees were cut down in order that outlaws could not find shelter. In most cases, however, Celtic improvidence was, we imagine, the cause of that absence of wood which strikes every visitor while travelling. The late Dr. R. D. LYONS endeavoured while in Parliament to urge the necessity of planting in Ireland. He was not immediately convincing, but in the last few years encouragement has been given to operations of the kind. A department of Forestry Statistics has been established, which must at first offer only sinecures to the officials. From the returns it appears that in 1894 1,492 statute acres were planted with trees, of which 286 acres were in Leinster, 487 in Munster, 395 in Ulster and 324 in Connaught. In the year ended June 30, 1893, the area planted was less, being 1,111 acres. The total number of trees planted on the 1,492 acres in the year 1893-94 was 3,069,586, viz. 666,794 in Leinster, 893,475 in Munster (of which 457,128 were in Waterford), 236,590 in Ulster, and 1,272,727 in Connaught (including 1,052,253 in Galway). Larch, fir and spruce were the trees chiefly planted. The total area planted in the year ended June 30, 1894, being 1,492 acres, and the area cleared 1,675 acres, there would appear to have been 187 acres less under woods and plantations in the middle of 1894 than at the corresponding period of 1893. Of the 933,021 trees felled 397,889 were used for "propping," which appears to have been the chief purpose to which the timber of almost all descriptions was applied. As regards the disposal of 152,468 of the 933,021 trees felled, it is reported that they were "used locally," and there were 247,950 (including 174,081 in Munster) which were "exported."

THE committee of the Liverpool Corporation report that the work of the Walker Art Gallery, as regards the various exhibitions held and the attendance of the public, may be regarded as of a satisfactory and gratifying nature. The need of an enlargement of the Gallery is becoming a pressing necessity. The curator is at present unable to display many valuable and interesting art objects for want of wall space; and it is believed that owners of valuable works and wealthy citizens generally are deterred from presenting pictures on account of the obvious want of suitable accommodation. During the year the Gallery was open on 340 days (including Sundays), the total number of visitors being 469,769, or a daily average of 1,381. This total includes 66,556 visitors who paid for admission to the Autumn Exhibition, and 10,827 pupils of schools of various denominations admitted free. The Sunday attendance was 29,844, being an average of 746. The Corporation purchased *A Mower*, a bronze statue by Mr. THORNYCROFT, R.A.; *The Finding of the Infant St. George*, a painting in oils, by Mr. C. M. GÉRE; *Eve and the Voices*, by Mr.

ROBERT FOWLER; *Ariel*, water-colour, by Mr. J. A. FITZGERALD. The donations to the Gallery included:—*In Clover*, by Mr. ROBERT W. MACBETH, A.R.A.; group, *Rugby Football*, plaster-bronzed, by Mr. BENJAMIN CRESWICK; *View of the Liverpool Town Hall*, by Mr. JOHN BARTER; *The Port of Liverpool*; two charcoal drawings, *Bishop of Ely* and *St. Jude*, by the late Mr. FORD MADOX BROWN.

ALTHOUGH JEAN MARC NATTIER was in the middle of the eighteenth century one of the most admired portrait-painters in Paris there are few of his works in any of the public galleries. Hence the great interest which has been excited among amateurs by the discovery of his portrait of the Dauphiness MARIE JOSEPHINE of Saxony. As at Versailles it was ascribed wrongly to another artist in the catalogue, there is no surprise that the evidence of its association with NATTIER was ignored. It was painted in 1751. The artist was then in his sixty-sixth year. NATTIER in 1715 was invited to Russia by PETER THE GREAT. But he went no further than Amsterdam, where he found the Czar. For him he painted a *Battle of Pultowa* and some portraits. PETER wished to bring him to Russia, but NATTIER declined. After 1720 he confined himself to portraiture, in order more quickly to gain money, for all the savings of the earlier part of his career were lost in the speculations which JOHN LAW inspired. The Court of LOUIS XV. and the most eminent personages of that period were depicted by NATTIER.

RAILWAY directors in France appear to care as little for the amenity of cities as great men of the same class in other countries. A few days ago M. PAUL SEDILLE with other architects and members of the Société des Amis des Monuments Parisiens, waited on the Minister of Public Works to bewail the destruction of more than three hundred and fifty trees on the Esplanade des Invalides. They were sacrificed in order to make the operations for building a railway station more easy. The French Parliament had declared that nothing was to be done which would affect the perspective of MANSART'S masterpiece, but in France, as elsewhere, all interests must succumb to the locomotive. The Minister joined in the lamentations of the Amis and informed them that he at least was resolved no structure should be raised which would diminish the beauty of the Esplanade. But he also will either have to submit to destiny or to enter into a contest not only with the railway company but with the guardians of the water-supply, and either body is stronger than any of the modern ministers.

THE architect to the Local Government Board, Mr. GORDON SMITH, appears to be an enemy to competitions. This peculiarity was made evident during the week. According to the *Leeds Mercury*, at a meeting of the Leeds Board of Guardians a week ago the proposed extensions and alterations at the workhouse were under consideration, and a resolution was moved to the effect that an architect be appointed to confer with the building committee and Mr. GORDON SMITH on the matter. An amendment was also moved that competitive plans for the alterations and extensions be invited from architects, and on a vote being taken the amendment was carried. At the conclusion of the business at the weekly meeting on Wednesday the subject was referred to by one of the guardians, who stated that on Monday afternoon, after the meeting of the building committee at the workhouse, two members of the Board had a short interview with Mr. GORDON SMITH, and when the question was put to Mr. GORDON SMITH as to whether there should be competition or the appointment of an architect, he most decidedly condemned competition; and, when asked for his reasons, gave them in a most business-like manner. In consequence it was suggested that the guardians who were in favour of competition might see their way to rescinding the resolution after hearing the opinion of Mr. GORDON SMITH. The matter was referred back to the committee for reconsideration. It would be interesting to know what are the reasons for departing from a system that has been found advantageous in so many parts of the country, and whether interference of this kind comes within Mr. GORDON SMITH'S official duties.

ENTRY OF ALEXANDER THE GREAT INTO BABYLON.

THE painting from which the illustration was taken is one of five or, as some say, six, devoted to the history of ALEXANDER the Great, which LE BRUN produced about 1673. They were to be reproduced in tapestry at the Gobelins. LE BRUN was superintendent of the factory from the time when it was taken over by LOUIS XIV.

The scene at Babylon depicted by LE BRUN does not suggest the entry of a conquering hero, for all the people appear to welcome him. The artist's interpretation cannot be said to be incorrect. According to PLUTARCH, the whole province of Babylon submitted to ALEXANDER as he passed through it on his march to India. On his return it would not be remarkable if, as QUINTUS CURTIUS says, outside the city the route was adorned with flowers and crowns, that silver altars with perfumes burning on them were to be seen along both sides, nor that the Babylonian poets turned out in a body to welcome ALEXANDER with chants they composed for the occasion. If all opposition was not more vigorous than in Babylon, the reputation of ALEXANDER as a warrior would not stand on a firm basis. He entered the city, but, says PLUTARCH, "he lived mostly in his pavilion without the walls, and diverted himself with sailing up and down the Euphrates, for he was much disturbed in his mind by repeated omens." Whether ALEXANDER died from the effects of a long carouse, or from the insanitary condition of the undrained region around the city, or from other cause, is not to be ascertained.

MONTAIGNE, when he declared that ALEXANDER was one of the three most excellent men in the world (the others being HOMER and EPAMINONDAS), justified his choice on the ground that nobody else accomplished so much in so limited a time. Undoubtedly it was remarkable for a man who died at thirty-two to have conquered nearly all of what was then known as the habitable globe. His faults, too, may be condoned, as MONTAIGNE recommends, on account of his youth and the strange prosperity of his fortune. But the pride, pomp and circumstance of war have lost much of their importance in modern eyes, and if ALEXANDER is still appreciated it is on account of his efforts as an agent in civilisation. He was the means of introducing Greek ideas into a great part of Asia, and if they were not enduring in their effects he was not responsible. In return something may have been drawn from the East by his army. Moreover, he must be credited with a share in the foundation of the School of Alexandria, which for a long period held the position once occupied by Athens. On that subject the late Cardinal NEWMAN, in one of his essays, wrote :—

Alexander, if we must call him a Greek, which the Greeks themselves would not permit, did that which no Greek had done before, or rather, because he was no thorough Greek, though so nearly such by birthplace and tastes, he was able, without sacrificing what Greece was, to show himself to be what Greece was not. The creator of a wide empire, he had talents for organisation and administration which were foreign to the Athenian mind, and which were absolutely necessary if its work was to be carried on. The picture which history presents of Alexander is as beautiful as it is romantic. It is not only the history of a youth of twenty pursuing conquests so vast that at the end of a few years he had to weep that there was no second world to subjugate, but it is that of a beneficent prince, civilising as he went along, both by his political institutions and by his patronage of science. It is this union of an energetic devotion to letters with a genius for sovereignty which places him in contrast both to Greek and Roman. Cæsar, with all his cultivation of mind, did not conquer to civilise, any more than Hannibal; he must include Augustus in himself before he can be an Alexander. The royal pupil of Aristotle and Callisthenes started where aspiring statesmen or generals terminated; he professed to be more ambitious of a name for knowledge than for power, and he paid a graceful homage to the city of intellect by confessing, when he was in India, that he was doing his great acts to gain the immortal praise of the Athenians. The classic poets and philosophers were his recreation; he preferred the contest of song to the palestra; of medicine he had more than a theoretical knowledge, and his ear for music was so fine that Dryden's celebrated ode, legendary and objectionable in its subject, only does justice to its sensitiveness. He was either expert in fostering or quick in detecting the literary tastes of those around him, and two of his generals have

left behind them a literary fame. Eumenes and Ptolemy, after his death, engaged in the honourable rivalry, the one in Asia Minor, the other in Egypt, of investing the dynasties which they respectively founded with the patronage of learning and its professors.

Ptolemy, upon whom, on Alexander's death, devolved the kingdom of Egypt, supplies us with the first great instance of what may be called the establishment of letters. He and Eumenes may be considered the first founders of libraries. A library, however, was only one of two great conceptions brought into execution by the first Ptolemy; and as the first was the embalming of dead genius, so the second was the endowment of living. Ptolemy determined that his teachers of knowledge should be as stationary and as permanent as his books; so, resolving to make Alexandria the seat of a *studium generale*, he founded a college for its domicile, and endowed that college with ample revenue.

CHARLES LE BRUN was the son of a sculptor, and was born in Paris in 1619. He studied under PERRIER, NICHOLAS POUSSIN, and others. In 1642 he was sent to Rome by his patron, the Chancellor SÉGUIER. There he remained for more than four years. LE BRUN was one of the artists who took part in establishing the Académie Royale, and held all the offices. In 1649 he was selected by FOUQUET to decorate the Château de Vaux, where he met the Cardinal MAZARIN, by whom he was introduced to LOUIS XIV. His ability received a fresh development in the works which were commissioned by the king, and he became the most characteristic type of the artists whose mission it was to make LOUIS appear as a sort of demigod. Architecture, painting and sculpture in connection with the palaces are evidence of his influence, and works approved by the Grand Monarque became examples which loyal subjects were proud to imitate. LE BRUN lived until 1690.

THE WESTMINSTER FRESCOES.

DURING the session of 1894 the attention of the First Commissioner of Works was directed to the condition of the frescoes in the Palace of Westminster, more especially those in the Queen's Robing-room. Accordingly Mr. H. Gladstone consulted the President of the Royal Academy on the subject, and he advised that, in the first instance, Professor A. H. Church should be asked to examine and report upon the state of the works, who at once placed his services gratuitously at disposal. During the course of the autumn he gave much time and attention to the work, and from time to time furnished reports containing much valuable information and advice. The purpose of the Professor's commission was to ascertain the condition of the paintings and to diagnose the causes of decay, where such was found to exist, with a view to obtain data on which to found recommendations for subsequent measures of preservation and, so far as might be desirable, of restoration. Accordingly he confined his operations to cleansing the paintings, and to some limited and temporary treatment of defects. He is now keeping those frescoes that he has dealt with under observation, and has promised a further report after the lapse of a certain time, when he will be able to judge how the paintings have been affected by the processes employed by him.

In his first report, dated August 14, Professor Church says :—

On the 9th and 10th instant I again visited the Palace of Westminster. On these occasions I confined my attention almost exclusively to the paintings in the Royal Gallery and in the Peers' Robing-room.

The two water-glass (or stereochrome) pictures in the Royal Gallery are in a generally sound condition, but obscured in different degrees by a white efflorescence. The first attempts to remove this seem to have been made in the year 1875; they were repeated down to the year 1888. Subsequently a current of air from bellows only has been applied to these pictures. On repeating the process of cleaning adopted by Mr. Richmond in 1875, I found that it effected a great improvement, and that the colours were firmly adherent in those parts of the work which I examined. I am inclined to recommend that both the *Wellington* and the *Nelson* should be forthwith submitted once again to this cleaning process, which consists in flicking the surface with a soft linen handkerchief containing a pad of carded cotton. It will probably be found necessary to supplement this treatment by the use, in some places, of soft brushes. It would not be safe to entrust these operations to an ordinary workman, but I recommend that Mr. Redhead, an assistant of Messrs. Shrigley & Hunt, of Lancaster and London, be engaged. I recommend Mr. Redhead because he is an experienced and careful operator who has done excellent work under my direction when cleaning Mr. Watts's large fresco in the hall of Lincoln's Inn.

I beg now to direct your attention to the two pictures in the Peers' Robing-room. These are by Mr. Herbert, one of them, the *Moses*, being painted in water-glass, the other in oil on

canvas. Both are in a sound condition, but are dirty. The *Moses* is obscured in a few places by a white efflorescence which should be removed by flicking and brushing. Afterwards the whole surface should be cleaned by means of soft bread. I have tried this treatment upon the face and shoulder of one of the figures (a boy), and find that it restores the obscured part to its pristine beauty. The chief places where this white film exists are the crevices of some mountains in the background and some of the shadows.

Mr. Herbert's later work (completed 1880) is in oil. It requires careful cleaning with distilled water on sponges or carded cotton pads. Subsequently it should be washed with a solution of peroxide of hydrogen in water, in order to brighten some parts of the paint which are slightly discoloured. It may be expedient to coat the parts of the paint which are slightly discoloured. It may be expedient to coat the whole picture with a light coat of mastic varnish, but this operation should not be carried out if a shining surface would injure the appearance of the work. As an alternative, I should propose a very light coat of "paraffin-copal medium," which will leave a dead surface and yet bring the whole picture together and enrich its colours. I should advise that the two pictures in the Peers' Robing-room should be cleaned by Mr. Redhead under my supervision.

A few remarks as to other paintings in the Palace of Westminster may be here added. The frescoes in the Upper Waiting Hall are in a deplorable condition. So early as 1871 Mr. Horsley pronounced his work and most of the others there to be "utterly dilapidated;" he begged that they might be screened from public view. For my own part I do not think that there is enough left of them to admit of their being restored.

The paintings in the Queen's Robing-room, which have been repaired, cleaned and coated with size and then with paraffin, present many pale patches and are greatly disfigured thereby. I have deferred examining them in detail until my return to London at the end of September, when I hope to be able to suggest some remedial measures. Nor can I at present express an opinion as to the paintings in the House of Lords. I think, however, that the oil-paintings in the Prince's Chamber and in St. Stephen's Chapel would be improved by washing with distilled water in the manner previously described, cleaning with bread following.

If my recommendations as to the paintings in the Royal Gallery and in the Peers' Robing-room be approved by the First Commissioner, I will gladly superintend the proposed operations this autumn, beginning in October, say, on Monday the 1st. I should be pleased to give my services. I venture to suggest that it would be judicious to commence by treating one only of the four pictures referred to in this paragraph, and to extend the operations provided that the first experiment proved satisfactory.

In a Memorandum, No. 1, dated October 20, concerning the wall-paintings in the Royal Gallery, the Professor writes:—

The work of cleansing the two water-glass (stereochrome) wall-paintings, by the late D. Maclise, R.A., was begun under my superintendence and after a series of experimental trials on Tuesday, October 2.

The painting first operated on was the *Wellington*, which the artist completed in the year 1863. This picture, which measures 45½ feet by 12, had shown at least as early as 1872 marked signs of deterioration, for in that year Mr. (now Sir Frederick) Abel was asked to report as to the advisability of applying a solution of paraffin to protect its surface from further change. In the following year the late Dr. Percy, F.R.S., was requested to examine into the causes of the decay. In 1875 both this picture (the *Wellington*) and the *Nelson* were cleaned by flicking them with silk dusters under the direction of Mr. Richmond, R.A. In 1878 Mr. Taylor (the Board's surveyor) described the *Wellington* as most unsatisfactory in condition; subsequently Mr. Richmond repeated the cleaning as carried out by him in 1875. This treatment was several times resorted to until the year 1888, when an officer of the Board reported the *Wellington* to be in a very bad state, but *Nelson* not nearly so bad.

I am given to understand that since 1888 an air-blast from bellows has been used with the object of removing dust from both paintings.

On examining this painting in August 1894, I found that it was generally in a sound condition but obscured in many places and over large areas by a grey film, which was especially conspicuous in the shadowed and darker parts of the work. This grey film consisted of a sort of efflorescence, which on analysis proved to contain the sulphates of calcium, potassium and sodium, with traces of ammonium compounds; some silica was also present in it. Moreover, the entire surface of the painting was darkened by a deposit from London smoke.

The colours underneath the above-named films of saline matter and of soot or smoky deposit were firmly attached to the plaster, except in a very few small spots and in a large number of exceedingly minute points in the darkest shadows.

It was ascertained that these disturbances of the pigment were not increased by flicking the surface with pads of cotton-wool enclosed in old soft linen handkerchiefs, nor by sponging with abundance of distilled water. In consequence, these flicking and sponging operations were carried out with great care over the entire surface, with the result that the greater part of the grey incrustation and of the sooty coat were finally removed. The water wrung from the sponges used in the final washing was but slightly discoloured, although the first washwaters were of an inky blackness and deposited a thick sediment of the same hue on being allowed to stand.

The operations were conducted by Messrs. Redhead and Drinkwater, skilled employes of the firm of Messrs. Shrigley & Hunt, of Lancaster and London.

These remarks as to the cleansing processes and as to the condition of the paint are applicable to the *Nelson*, which was finished in 1865, as well as to the *Wellington*, with the exception that a blue pigment and a deep red pigment in the former painting were found to be rather loosely attached, and in consequence were excepted from the treatment. The operations on these two pictures occupied fifteen working days, and were completed on October 18.

During the progress of the work I was present to watch and direct the operations on ten occasions. I may add that both pictures have been greatly improved in appearance by the treatment to which they have been subjected. The obscuration of many large areas has been wholly or partially removed; numerous lost details have become visible; while the lighter parts have been brightened and the shadows deepened.

The future treatment of these important and interesting paintings remains for consideration. I should recommend that both of them should be syringed with distilled water after the lapse of a few months, and that subsequently they should be systematically freed from dust, &c., by the use of bellows and clean new feather brushes.

I am not prepared at present to advise their treatment by a preservative and waterproofing solution of paraffin wax, although its application would undoubtedly enrich the shadows and protect the surfaces. But if the grey deposit were again to be formed it would be very difficult to remove it after the application of paraffin.

But there can be no question about the desirability of maintaining a fairly constant temperature in the Royal Gallery. I attribute the deterioration of these paintings mainly to the frequent deposition of moisture on their surface, this moisture carrying with it not only suspended soot and dirt but also dissolved sulphuric acid from the atmosphere. This compound, derived from the combustion of the sulphur in coal and in gas, has formed sulphates with the basic materials on the painted surface, and has given rise to the chief constituents of the "grey film."

I cannot learn that these pictures have ever been washed * since they were first executed, although the inventor of the stereochrome method of painting recommended the liberal application of distilled water to the finished picture.

I propose to place on record in a second Memorandum some observations on the two paintings by the late J. R. Herbert, R.A., in the Peers' Robing-room. These are now undergoing the treatment which I have advised.

In a Memorandum, No. 2, dated October 26, concerning the wall-paintings in the Peers' Robing-room, the Professor writes:—

The work of cleansing the water-glass (stereochrome) picture by the late J. R. Herbert, R.A., representing *Moses and the Tables of the Law*, was begun, under my superintendence and after a series of experimental trials, on Friday, October 20. This painting, which was completed by the artist in the year 1864, was in a generally sound condition, but obscured by much dirt, and in a few places by the grey film described in Memorandum 1. It was cleaned by means of bread, but the grey film was removed by the flicking process already described. Finally, the picture was sponged with distilled water, except that the areas where a certain red pigment had been used were merely dusted with a soft brush, as the colour would have been partially removed had water been freely applied to the surface. A few small patches, whence the pigments had flaked off, were not treated in any way, but their presence does not detract from the beauty of this fine work as ordinarily seen from the floor of the room. I believe that the painting has not been cleaned since its completion, thirty years ago. That it had suffered somewhat in the course of time is evident from the statement which I find in the report on the frescoes made in 1888 by an officer of the Board, that Mr. Herbert had asked in that year to be allowed to repair it. I consider that it has now recovered to a very considerable extent its original effect.

The other picture in this room was completed by Mr.

* I have been informed that these pictures were washed with ordinary water (warmed) in the year 1875. This water, drawn from the well in the Palace of Westminster, is highly charged with saline matter, and is unfit for the purpose.

Herbert in 1880. It represents the *Judgment of Daniel*, and is painted in oil on canvas. It was first thoroughly washed with distilled water, and then the whole surface was gone over with a pad of cotton-wool moistened with a little pale drying linseed-oil free from lead, all excess of oil being afterwards removed by means of clean pads of dry cotton-wool. The effect of this treatment has been a most remarkable improvement in the colours and the general effect of the work, which may now be said to be in perfect condition.

The cleaning operations on the two paintings in the Peers' Robing-room were completed on the morning of October 26.

I venture to suggest that the *Daniel* should be framed with a wooden moulding similar to that of the *Moses*. At present the gap between the edge of the picture and its architectural framework detracts greatly from its appearance.

In a Memorandum, No. 3, dated November 23, concerning the wall-paintings in the Queen's Robing-room, the Professor writes:—

The cleaning of the series of wall-paintings (painted in true fresco by the late W. Dyce, R.A.) in this room was commenced on the afternoon of Friday, October 26, 1894. The work first taken in hand was that entitled *Mercy*, which occupies the eastern compartment of the north wall, and is 11 feet 2½ inches in height by 10 feet 2¼ inches in breadth. It was painted in 1854. The late Mr. Cope, R.A., in the year 1868, cleaned this picture and repaired and repainted parts of it. The cleaning was effected by means of bread; the decayed parts were removed and some of the heads and hands were restored in water-glass. The entire surface was then coated with parchment size, any small injuries being touched up with size-colours. Finally, the painting was treated with a solution of paraffin wax in benzol. Mr. Horsley in 1873, and an officer of the Board in 1888, reported this and the other wall-paintings in this room to be in a comparatively good condition. But I found, in 1894, that not only was there much dirt on this picture, but that there were more or less conspicuous defects of three kinds in parts of the surface, namely, an opaque grey film, patches of a light brown hue, and actual exposures of the white ground. Sponging with distilled water removed much of the grey film, and lessened the disfigurement caused by the presence of the brown stains; the bare places were touched up with pigments mixed with egg-yolk, but these additions of colour were quite insignificant in extent, and did not affect any important part of the work. In order to lessen the unpleasant effect of the brownish patches on the light parts of the blue robe of one of the principal figures a little soft pastel chalk was applied to them. This is confessedly a temporary measure, for the colour can be instantly removed by a soft dry brush, but being in hopes of discovering some method of removing the brownish patches, I was unwilling to conceal them by any more permanent kind of repaint.

The large painting, *Hospitality*, on the north wall (11 feet 2½ inches by 22 feet) was next taken in hand. The surface was first washed with distilled water, by which much dirt and some of the grey film which obscured many parts of the work were removed. It was, however, found that the surface of this painting, especially towards its western end, was in several places in a soft and decayed condition, the pigments being loosely attached to the ground and the plaster rotten. These defects culminated in the light-coloured jerkin of a man's figure. Moreover, it was found that the grey obscuring film before mentioned could not be entirely removed, and remained conspicuously evident on the legs and feet of many of the figures.

The injuries which this fresco has suffered are the more remarkable since, in 1875, Mr. Horsley reported this and the other frescoes in the room to be in a comparatively good condition, such report being endorsed by the Board's officer in 1888. Mr. Cope had, indeed, in 1868, reported the fresco under discussion to be in a perfect state, but then it must be remembered that the artist had completed it only four years previously. However, Mr. Cope did cause it to be treated with a solution of paraffin in benzol in the year 1868.

I have now had the places in this large fresco where the colour had been lost touched up with tempera pigments, while the whole surface has been treated with a solution of which paraffin wax is the chief constituent. I felt that this treatment was the only one open to me, on account of its having been already adopted by Mr. Cope in 1868. I must, however, add the statement that the presence of paraffin in the superficial layer of this painting was scarcely perceptible, although I do not doubt that this hydrofuge substance has exerted a certain protective influence on the work.

The three remaining frescoes in this room (on the west wall) were treated exactly after the same manner as that just described. All three pictures were extremely dirty, and in each certain parts were in a decayed condition, some of the pigments having become blistered or detached. The defective places were repainted in tempera colours, and then the whole surface was treated with a weak solution of paraffin wax and copal in toluol. These frescoes were originally painted in the years

1851 and 1852. In 1868 they were cleaned and repaired by Mr. Cope, who cleaned them with bread, removed the decayed parts, repainted some portions with water-glass and the smaller injuries with size colours, covered them with parchment size, and gave them a final coat of paraffin in benzol. Having found that there were several portions of the lighter parts of the draperies in all the frescoes in this room which exhibited the light brown patches already noticed in this memorandum as occurring on the blue robe of one of the figures in the picture of *Mercy*, I finally decided to touch up these portions with tempera colours, so as to conceal these unsightly but irremovable stains.

The result, thanks to the skill and care of Messrs. Shrigley & Hunt's assistants, has been, in my opinion, entirely satisfactory.

It is scarcely necessary to say that no more paint has been used than was absolutely necessary.

The work in this room was completed on November 23. During its progress, however, the oil-paintings in the Prince's Chamber were washed and slightly oiled with drying linseed-oil, free from lead, so that the treatment of the five paintings in the Queen's Robing-room did not occupy the entire period between October 26 and November 23.

In concluding this series of memoranda I may be permitted to observe that I will gladly superintend any future and further treatment that may be required by the two paintings by Maclise in the Royal Gallery. I believe that these would be easily brought back to their original brilliancy and depth by the application of the paraffin solution, provided that no fresh grey film reappears upon them during the next few months. The treatment of three of the pictures in the House of Lords, and of five out of the sixteen paintings in the Peers and Commons' corridor is desirable. This work may well be deferred until the late summer of 1895. I should like to repeat once more, and very emphatically, my recommendation that every effort should be made to maintain a uniform temperature of not less than 60 deg. Fahrenheit in the Queen's Robing-room and the Royal Gallery.

THE "ROSY CROSS" EXHIBITION IN PARIS.

A CORRESPONDENT of the *Glasgow Herald* gives the following account of his experience with a society of eccentrics:—

The artistic Society known as the "Rose Croix" sprang into existence some years ago, and annually ever since its formation we have been favoured with an exhibition of artistic works of the ethereal, exalted class, which some people admire, or allow it to be thought they admire, but the real meaning or nature of which few can grasp.

The gentleman who goes by the name of the "Sar Peladan" is the high prophet of the Society. He has painted pictures of a very mystical description and he has written books intended to elevate human nature which are queer reading, and are beyond the comprehension of the average reader. The Sar Peladan has the head of a typical Christ—long beautiful hair of which he makes the most, the beard of a saint or "mage," the eyes of a man who is always in dreamland and among the poets. Formerly he used to dress in an eccentric manner, in harmony with his appearance. He wore black silk garments fitting loosely to a well-made person, long yellow leather boots and the headgear of an idealist. He used to be considered as a species of literary and artistic maniac, using language no one else used and presenting at his annual picture exhibition works which raised a smile when they were intended to elevate and purify the minds of the spectators. Gradually, however, the "Sar" has consented to descend in certain matters from the lofty regions of the ideal and to dress more like the common run of men. He has cast off the flowing silken garments and the long yellow boots and appears in public in a well-made suit of clothes with neat varnished boots.

For the varnishing-day at the Salon of the Rose Croix, I received an invitation to be present in the usual rather strange form, "The Order of the Rosy Cross, of the Temple, and the Grail. The Grand Master, Sar Peladan, invites you to the varnishing for the Fourth Salon of the Rosy Cross." The first exhibition of the kind, I recollect, was a much bigger affair than that of this year. In fact, each succeeding year the show of pictures has become more limited, and the place in which they are shown smaller. But, if the quantity is less, the quality is distinctly better. This year the Salon of the Rosy Cross is installed in the Rue de la Paix.

The room in which the idealists, who are fervent in their admiration for the "Sar" and members of his Society, exhibit their productions was crowded to overflowing on varnishing-day, and, as usual, the full-length portrait of the "Sar," in flowing robes and flowing locks, was to be met with everywhere. The best one is done by the Belgian artist, Delville. At the opening of the varnishing day some one had placed at the foot of the picture an incense-holder, from which

rose clouds of perfumed vapour and smoke. The "Grand Master" himself, with becoming modesty, had it removed.

Some of the paintings on view, although the work of originals, such as the members of this Society most undoubtedly are, have none the less, at any rate in a few cases, real merit. There are some very beautiful decorative figures from the brush of M. Charles Maurin, and a fine study of a woman dreaming at the edge of a pond, by M. Point, who also exhibits some very curious drawings. *A Night Reverie*, by M. Osbert, is suggestive and reposeful. *The Elements*, some subjects for stained-glass, by M. Adrien Duthoit, are good; and praise is due to M. Maurice Chabas for his work called a *Mythological Vision*. The *Flowers of France*, an allegorical vision by a painter whose name does not appear in the catalogue, is also a work of some merit.

It goes without saying, seeing the exalted and impossible theories which characterise the Sar Peladan and his faithful followers, that there are numbers of exhibits which are simply grotesque, both as to colouring and composition. Long lean women in long flowing garments, the figures being almost transparent, in the midst of most prodigiously long trees, violet, blue, saffron coloured, are to be met with, and one member of the Society has perpetrated a moonlight landscape of a very queer colour, which he calls *The Moon with a Cold in its Head*, or something to that effect. In the sculpture department there are one or two good things by Marquet de Vasselvt, and altogether, as I have remarked, though the show is smaller than it used to be, it is better, extravagance and eccentricity notwithstanding.

The "Sar," in a preface to his catalogue this year, intimates that if hitherto he leant towards excessive eccentricity and sensationalism, it was to attract and rivet the attention of the heedless multitude, which he now hopes to retain for his "cherished ideas and ennobling artistic reforms." In a word, he says, "he is about to abdicate in order to govern better," by which it is probable he means that he and his followers will patronise less wildly extravagant theories and consent to humanise themselves.

Amongst the people who filled the exhibition on the first afternoon were some very curious types. In fact most of the visitors present seemed to have a sort of relationship with the shadowy fading-away kind of pictures on the walls. Amongst the men, the majority of whom wore their hair long, was a personage draped in one of those cloaks known by the name of "Talma," and wearing round his neck a violet velvet cravat. He was evidently on the best terms with himself, but I doubt, out of carnival time, if he could have ventured to walk down the boulevards thus attired. There were also present several young girls with long braided hair, and three young persons of the fair sex who, standing together in a group, drew from an Englishman present the remark, "They are more mad-looking and delightful than any of the pictures." One of the three had her flaxen hair pulled down flat on either side of her face to the chin, and wore a curiously-wrought silver casque on her head. Her long thin arms and flat bust were encased in a silver-wrought jacket, which looked as if it might have been taken from a museum, and her faded velvet skirt, pale in hue, hung closely about her limbs. Her two friends were equally out of touch with the style of the present day.

TREASURE TROVE IN ROME.

ON the Pincian Hill, in Rome, writes a correspondent of the *Scotsman*, I lately witnessed a scene which would have delighted the soul of Professor Blackie and educationists of his school. It was a municipal teacher at the head of about a dozen little boys giving instruction *al fresco* from the busts of the mighty dead which adorn that loveliest of gardens. These busts, I may remark parenthetically, were put up at the instance of Mazzini during the short-lived Triumvirate of 1849, and have been added to from year to year, until the Pincian has become a Valhalla of all that Italy has produced of great or good from the earliest historic era to the present. The little group, consisting of the teacher and his pupils, drew up before the bust of Marius—a fine reproduction of that plebeian soldier whose vigorous, if unscrupulous, personality left its mark so deeply on the destinies of Rome, and one of the boys was asked to tell his class-fellows all he knew of the hero. This he did in good, set language, evidently the result of the previous night's preparation, and then another boy was invited to tell whatever more he knew in supplement to the narrative of his predecessor. From Marius the itinerant class then moved to Sulla, and thereafter to Pompey and Julius Caesar, the same process being gone through in each case, namely, the recital of a *viva voce* account of these great captains, in presence of their "animated busts." In this way an epoch-making chapter of Roman history was gone through in something less than an hour, without the aid of books, in the fresh morning air, and as the incident of an invigorating walk.

As I returned to my hotel, I could not help thinking how much the scene I had witnessed would have gratified the kindly educationist we have just lost, how fully it would have squared with his preference of *viva voce* to bookish instruction, with his love of artistic object-lessons in substitution for printed words, with his delight in open-air exercise taken conjointly with mental training. Of course, climatic conditions north of the Alps yield far fewer opportunities for this outdoor "palæstra" than the steadier, kindlier sky of Italy; but this drawback, as Professor Blackie would have promptly suggested, could be to some extent overcome by the "porticoed hall," open to the atmosphere but not to the rain, of which we are not without examples in the British Isles.

Apart, however, from its hygienic side, this learning of history in presence of its architecture or statuary is one which makes a well-employed visit to Rome or Athens of unique value in these days. Compare, for instance, the vivid impressions one receives from perusing Suetonius, or the Augustan history, or Herodian, in the palace of the Cæsars, the Forum, the Sacra Via and the Colosseum with what one derives from the same perusal in the arm-chair, particularly if the former be supplemented by immediate reference to the coins, the inscriptions and the busts of the long succession of the Cæsars. Such an advantage to the student of history explains the force of Dr. Johnson's dictum that no man's education is complete until he has visited the shores of the Mediterranean—a dictum which, if true in the doctor's day, is infinitely truer now when the excavator's mattock has brought to light a new world of Classical treasure as eloquent of the "long result" of antiquity as any palimpsest discovered in Egypt or parchment disinterred on Mount Athos.

Decade by decade Rome is adding to this exhumed world, and now there are three storehouses in which it is on view—the Museo Preistorico at the Collegio Romano, the Suburban Museum at the Villa Giulia, and latest and in some respects richest of the three, the Museo Nazionale Romano, inaugurated in the Baths of Diocletian. This "great open book" of history and art consists of the relics dug up from the subsoil of Rome or fished up from the bed of the Tiber, reinforced by the results of excavation carried on in the Roman provinces or even further afield. Three Ministers of Public Instruction, in whose competence the subject-matter lies, have successively laboured at the Museo Nazionale Romano, but Dr. Baccelli, the most scholarly of the trio, was the appropriate medium by whom it was made *publici juris*. Let us enter with the distinguished company, headed by their Majesties the King and Queen of Italy, and take a survey of the beautifully-arranged halls in which the "antiquities" appeal to us. The first accommodates the treasure trove yielded by that "Pompeii on the Tiber," Ostia, and the eye is at once arrested by the two grand portraits of the Gordians, placed laterally on the noble altar, decorated with reliefs describing the legend of Rome. Of priceless value is the next object, the bust of the Emperor Vespasian, conspicuous near the window; hardly inferior being the other imperial likenesses, arranged each in its proper recess, and all coming under the classifying letter B. The next groups of objects, those marked C and D in their appropriate *locale*, consist of the monumental remains of the Arval Brothers—a collection of unique value for the history of the Roman religion, and for the chronology of the "principato Romano"—and reinforced by memorable stones dug up on the Via Cecilia or Salaria, such as the "libello di Eutichete" and the honorary marble erected to Lucius Julianus—relics these which occupy an important position in the series of Roman epigraphs—to say nothing of the famous "Bronzo di Campoattaro," near Benevento, saved by Signor Bonghi for the Roman collection, and dealing with the "alimentation of the children of the poor instituted by the Emperor Trajan." Indicated by the letter E is a fourth group, composed of marble bas-reliefs for the most part proceeding from the excavations on the Palatine, while one of the recesses is set apart for all reliefs of purely Greek workmanship. The fifth group, marked F, is rich in sculpture, the gem of the whole being a marvellous young faun by Praxiteles, brought to light in the Via Venti Settembre, not far from the War Office. Very beautiful also is the head of a statue of Penelope found in the excavations close to the Tiber Embankment, and in appropriate proximity to it are a multitude of female heads representing the various modes of tying the hair employed by the "grandes dames" of ancient Rome.

The collection, however, which is of most novel interest is that made by Dr. Baccelli, consisting of the barbarous relics discovered in the tombs of Castel Trasino, near Ascoli Piceno. Twenty-nine in number were these tombs, and their contents were mostly ornamental armour belonging to warrior chiefs, much of it beautifully chased in gold—splendid ear-rings, bracelets, necklaces, evidently of female use, and such like. Descending to particulars, you notice a great variety of daggers, highly ornamented; perforated lances, the anticipation of the Mediæval halbert; leathern shields with gold or gilt bosses, and "corazze brigantine." Returning to the female ornaments—unique, I believe, of their kind—you are struck with the rings

(wedding and other), the necklaces of polychrome enamel and long ivory combs of exquisite workmanship. Then there are coins of the Emperor Justinian, forming not the least precious part of a medley of treasure trove—half Byzantine, half barbaric—the property, in all likelihood, of those Lombards who for some years occupied Castel Trasino and its vicinity. This collection, it is needless to say, evoked very marked as well as very general interest, and will doubtless form the subject of discussions, not to say controversies, or even literary encounters, only less obstinate than those of the warrior chiefs from whose relics they will spring. But whatever divergence of opinion they may cause, the antiquarian and historical world will be unanimous as to the great value of those treasures, enriching with further illustration epochs comparatively well known, and filling up, as the Byzantine barbaric collection does, a tract of history of which the monuments have hitherto been poor or scanty. Rome by this Museo Nazionale has added another to her attractions; and Dr. Baccelli has, by the same institution, still further strengthened his claims on the gratitude of the scholar, the artist and the man of letters.

THE ART OF WILLIAM HOLMAN HUNT.

A LECTURE was delivered by Mr. Whitworth Wallis, the keeper of the Birmingham Museum and Art Gallery, at the Royal Institution, Manchester, on "The Art of William Holman Hunt." Mr. Wallis said that the history of William Holman Hunt was the history of that movement which had borne the oft-discussed and the oft-misunderstood and misrepresented name of pre-Raphaelitism. The story of the pre-Raphaelite movement was the story of four great artists, generous-minded and enthusiastic men; it was the story, too, of the enthusiastic effort of youth, for so determined were these young painters in their work that there could be no such thing to them as failure. Though the famous brotherhood lasted but a short time, and the founders themselves were later separated in aim, yet the movement so inaugurated had had a permanent and remarkable influence upon all contemporary English painting. Most of his hearers were doubtless acquainted with the origin of the movement, usually attributed to the finding at Millais's house of a book of engravings of the frescoes in the Campo Santo at Pisa, the purity, simplicity and poetic serenity of which had a powerful effect upon the three friends and young artists—Rossetti, Millais and Hunt. As they seached through this book of engravings they found, or thought they found, that freedom from corruption, pride and disease for which they sought. There was no trace of decline, no conventionality, no arrogance. Whatever the imperfections, the whole spirit of the art was simple and sincere, and was, as Ruskin says, "eternally and unalterably true." It was in the autumn of 1848 that a definite attempt was made to band together a little company of students and friends who were prepared to follow openly the principles of fidelity to nature. A meeting was held at Rossetti's studio in Newman Street, and seven members enrolled themselves under the title of the pre-Raphaelite Brotherhood. They were Dante Gabriel Rossetti, John Everett Millais, William Holman Hunt, William Michael Rossetti, F. G. Stephens, Thomas Woolner and James Collinson. The one principle which was at first their ruling one was that of painting everything from nature and from one model, and that should a picture need a landscape background original studies should be made as far as possible under the conditions of light which the subject required; that is to say, moonlight was to be painted, not imagined, and to this close attention to the effects of light we are indebted for the superb results of moonlight in the *Light of the World*, the mountains of Moab in the *Scapegoat*, and the effects of light on the landscape in Millais's *Autumn Leaves*, and on the riverside foliage in *Ophelia*. Mr. Wallis then referred with great feeling to Ford Madox Brown, who though never a member of the brotherhood was the teacher of Rossetti and Hunt, and the painter of two of the finest pre-Raphaelite works in the world, the *Last of England* and *Work*. Holman Hunt was born in London in 1827. His father was in very modest circumstances, and, seeing that his boy would have to earn his own living, he entertained the strongest objections to his becoming an artist; Mr. Hunt, sen., holding that artists, actors, authors and other low-class individuals were a dissolute, reckless, loafing lot of idle fellows. At twelve years of age young Hunt was taken away from school, where, by the way, he had scribbled more designs in his copy-books than exercises, and was placed with an auctioneer as a sort of probationary clerk. This auctioneer was himself fond of drawing, and, oddly enough, encouraged the artistic qualities of his clerk instead of inculcating commercial principles: At the end of a year and a half the auctioneer retired from business, and Hunt then occupied a stool in a little room looking on to three blank walls in the office of a Manchester warehouseman. There, to his delight, he made friends with a designer of calicoes, and tried his hand at his first designs. At

sixteen years of age he relinquished commerce, and took up art as a profession. It must have been a hard fight. He tried for admission to the Academy schools and failed; tried again, and his drawings were rejected. Then his father spoke seriously to him, said he was wasting his time; but young Hunt said he would try once more, and did so, this time successfully. He was then seventeen. Then commences his friendship with Millais and Rossetti, the finding of the book of engravings and the starting of the pre-Raphaelite movement. Mr. Wallis then described at length each of Mr. Hunt's principal works as they had been produced, commencing with the *Rienzi*, incidentally remarking that Dante Gabriel Rossetti sat for Rienzi, and Mr. Stephens assured him it was the best portrait executed of the poet-painter at that time. In speaking of the *Christian Missionary* and the *Two Gentlemen of Verona* Mr. Wallis referred to the ignorant and vulgar abuse showered upon the pre-Raphaelites at that time; but he truly said that not a word was remembered now, whilst the pictures so abused were now famous and the artists amongst the greatest of the age, the lecturer adding interesting features or circumstances connected with the production of several of Hunt's best-known works. In conclusion, he said that of all the English pre-Raphaelite painters Mr. Hunt had remained the most consistent, the most exclusive in his aims and methods. No artist who had ever lived had been so painfully and so thoroughly conscientious as Mr. Hunt. Every picture had been painted with the utmost of the artist's strength and the keenest of his emotions. He was one of the greatest painters of the age, and his pictures ranked amongst the noblest, the greatest and the finest in the world.

PRE-HELLENIC WORSHIP.

A PAPER was read by Dr. Phené, on "Researches and Excavations in Argolis, Phocis, Boeotia, &c.," illustrative of the pre-Hellenic worship of Greece, before the British Archaeological Association, on Wednesday in last week.

The lecturer said he had undertaken the researches for the elucidation of a subject not touched on by the Greek writers, nor by any modern historian or mythographer, but yet one which, from the evidences he had found in India, Persia and Asia Minor, promised to reward diligent search. He had extended his examination over many years, and had made repeated journeys to the different parts of Greece which, from certain semi-historical traditions, seemed most likely to be productive of result. To obtain the information he sought, he selected districts which Greek history indicated to have been those first occupied by the different tribal clans, which, in an independent condition, settled in localities noted afterwards for their mysterious rites, their ancient families, and their consequently powerful influence on surrounding tribes, and eventually their historical importance on Greece, taken in a collective sense. So much of actual history was shrouded in the myths of poets, dramatists, and even of historians, that it had been a fertile field for modern writers to unravel some of the clouds of romance in order to find nuclei around which they had cumulated.

Greece and Italy were, of course, among the first countries he (Dr. Phené) had searched for the evidences he sought as long back as 1856, when, taking advantage of the favourable European feeling to England and to Englishmen, in consequence of the war with Russia, he found himself everywhere welcome, and received much assistance from Government engineers and officials. But he had not then studied his subject as he afterwards did. Indeed there were no literary channels for doing so, and his subsequent surveys were successful from the experience his own investigations secured him.

Led by one or two unexpected successes, and noting carefully the physical surroundings in each case, he followed up his researches in different countries with similar success. No longer accidental, but the result of careful notation of the local histories, the ancient sites of worship, the species of worship, with often their historical overthrow, contestation for and not unfrequently restoration of the old faiths. These events were screened under political records, which so far had not been the source from which mythologists drew their ideas. They sought the myths, and with all their changes myths they continued to be; whereas, denuded of externals and put face to face with facts and with those unchanging features of their special localities, the mountain sites of worship, the archaeological remains and the actual political events known to have occurred, difficulties were brought down to what appears plain matter of fact, though still of mysterious import and often of sad reality.

The pre-Hellenic worship of Greece had either been passed over as unknown by mythologists, or only penetrated superficially by such broad thinkers as Mr. Gladstone, but it had been illustrated in an extraordinary manner by the exhumations by Dr. Schliemann. At Mykenæ access was granted to Dr. Phené, and his object being to study the mythological

relics, it need hardly be said that his careful personal inspection was a great elucidator of many pre-Hellenic features of the local worship of the district; though he paid four visits to Argolis and visited all the historical places both before and after journeys to Cappadocia, and in Asia Minor generally, before he arrived at conclusions which show the close connection between the exhumed relics and the early worship of this, the most ancient part of Greece, at least so far as actual tangible history informs us.

With such data at his command, he showed by drawings the close resemblance of the most ancient and most sacred places of worship, the nature of the worship and its attendant sacrifices, the objects worshipped confirmed by history, the introduction of new religions, the contest between the priestly and warlike elements, tending to the overthrow of the old and the institution of the new faiths, with alternate successes, restorations, defeats and re-establishment on both sides in different localities. And how gradually one or other successful myth maintained itself by amalgamating some of the features or emblems of a deposed priesthood and worship with its own, thereby softening the hostility of the sacerdotal party and avoiding offence to the political. Notwithstanding which these varying worships, although local bitterness was softened, still tended to separate politically the different states of Greece, so leading to the internecine wars which prevented a general amalgamation in a national sense, except in such cases as a common attack as that of Persia.

Although the most ancient localities were selected, as Argolis, Phocis, Boeotia, with their grand seats of worship at Argos, Mykenæ, Epidaurus, Sicyon, Delphi, Parnassus, Thebes and also Corinth and Olympia, yet not only did the external features agree, showing very careful selection of places for sacred sites, but the worship and sacrifices also agreed, as well as the localised nomenclature and descriptive names of the objects worshipped, quite apart from what is understood as Grecian mythology, and finally the actual relics exhumed, or described as once existing in the several localities, strongly confirmed the whole. In some instances the introducers of the different worships were identified and the countries whence they issued, to an extent tending to show ethnological affinities with early races. Dr. Phéné, however, touched very slightly upon these, being desirous to confine his subject to Greece and to the parts of Greece, in particular, which he referred to, though he stated that his investigations extended greatly beyond Greece and were general through Europe and Asia, and had been prosecuted at great expenditure of labour, mental resource and study, as well as financial outlay.

One of the religions referred to was that of the Cabeiri, which existed from the earliest times, long prior indeed to Hephæstos or Vulcan, its supposed founder. The influence of this cult was immense. Not only was it closely connected with the other worships of the pre-Hellenic times, but it influenced men's minds by combining the highest artistic workmanship of the age, such as goldsmith's work, jewellery, gem cutting, intaglio engraving and high class lapidary work, in short, all that mental culture and physical design with a great knowledge of metallurgic art also involved in its age. It would necessarily carry with it the influence of kings, potentates and warriors, from the manufacture of diadems, regalia and arms; while female influence would be enlisted for it under the charms of personal adornment. To dislodge such a worship, surrounded as it was with all the rites of terrible mysteries, was a task that truly Herculean power alone could embark in. Many points not directly connected with worship arose in the inquiry, as, for instance, the introduction of the orange tree into Greece, which came in under a merciful female influence, which fostered labour, agriculture and the reign of peace.

A collection of exhumed articles was exhibited primarily, examples of every kind of plain, coloured and decorated pottery, of which illustrations had appeared in Dr. Schliemann's publications, both of "Ilios" and "Mykenæ"; next, pottery which was unlike any excavated by Dr. Schliemann in Argolis, assimilating to that of Troy, which he admits none of his Argolic pottery did, and which was dug up near the small pyramids between Argos and the road to Epidaurus, and the foundations of demolished specimens of similar pyramids. Bronze articles, including a bronze horse and a clasp for harness or for a sword belt, a bronze mirror, &c., while from one of the deepest tombs in the Agora of Mykenæ, which from Dr. Schliemann's excavations appears to have been a tomb of royal priests, fragments of the bronze sceptres, which had been left behind when the great treasure was secured, but which were collected by Dr. Phéné, testified to the intense age of the deposits. In this tomb Dr. Phéné also found a remarkable object which Dr. Schliemann had overlooked, a material of an intensely blue colour, with a polished surface, apparently an imitation lapis lazuli, which probably formed a casket in which the two crystal orbs found in the same tomb were deposited. From Troy he exhibited, also for comparison, not only the pottery above described, but specimens of the most delicately-coloured and enriched Sidonian glass, a bronze

lamp and iridescent beads from the tumuli, with fragments of semi-calcined bones and teeth, whorls, loom, weights, &c.

The president, Mr. Loftus Brock, expressed great interest in the beautiful Sidonian glass from Troy and some finely-coloured and polished cement, exhibiting the richness of internal mural decorations of the structures of Argolis.

Professor Rupert Jones, F.R.S., F.G.S., explained the bones and teeth as those of the goat and the pig, the one sacred to Pan and the other to Demeter, both therefore probably sacrificial.

Mr. C. H. Compton proposed a vote of thanks to Dr. Phéné which was warmly responded to.

SOCIETY OF ARCHITECTS' EXAMINATION.

A RESOLUTION was passed at the special general meeting of the Society of Architects on October 30, 1894, that applicants for admission into the Society after November 1, 1896, should, with only two exceptions—viz. (a) Candidates who are not less than thirty-five years of age, and have been directly engaged professionally in architectural pursuits as principals for at least seven years; (b) Candidates who are not less than thirty-five years of age, and have been directly engaged professionally in architectural pursuits as assistants or as assistants and principals for at least ten years—be required in every case to pass either, 1. An examination held by the Society; or 2. One or more public examinations held by other bodies, which may be taken in lieu or partly in lieu of the Society's examination.

It was also resolved that the Council should publish the first list of qualifying examinations, and submit the same to the Society before March 31, 1895.

In submitting a first list of the qualifying examinations the Council desires to point out that it has considered and weighed all courses of instruction and examinations connected with the architectural profession in the United Kingdom, and would lay special stress upon the importance it attaches to a systematic and well-graded course of instruction. As, however, the terms of the resolution of the special general meeting only take into account an examination as an alternative to the Society's own examination, it has been found impossible to recognise certain courses and schools where thorough instruction, unaccompanied by a final examination, is given. On the other hand; it will be found that the Council has been able to include certain examinations which, it is glad to say, have been preceded by a prolonged course of instruction.

The Council also desires to announce that, in response to its representations, certain public bodies now holding courses of instruction in subjects similar to those of the Society's examination, but at present unaccompanied by a final public examination, have expressed their willingness to take steps whereby such a final examination may be established, so as to meet the Society's approval and requirements. It is therefore hoped that before long the list of alternative examinations may be extended and that certain deserving public institutions, already providing sound instruction in architectural subjects, may be happily and properly recognised.

All candidates seeking election into the Society of Architects will, with the exceptions previously noted, be required to satisfy the Council that they possess a competent knowledge of architecture, building construction and materials, and modern practice. The subjects of the examination to be held by the Society are as follows:—

Section I.—ARCHITECTURE.

Subject (a). *Architectural History*.—The general principles of the various styles and periods of architecture, their dates, mouldings and enrichments.

Subject (b). *Planning and Design*.—The plan and design of some building or portion of a building, with details to a larger scale.

Section II.—BUILDING CONSTRUCTION AND MATERIALS.

Subject (a). *Construction*.—Constructional details in all trades.

Subject (b). *Materials*.—The properties, methods of working, manufacture and the application of materials to building works.

Section III.—PRACTICE.

Subject (a). *Specifications*.—Preparation of specifications and the examination of builders' accounts.

Subject (b). *Contracts*.—The conditions pertaining to a building contract; the relative positions of architect, client and contractor; and other questions of ordinary practice.

Subject (c). *Sanitary Science*.—To include water supply and drainage, ventilation, lighting and heating of buildings.

The Council further proposes to accept in lieu of the Society's own examination:—(1) A certificate of having passed the examination qualifying for the associateship of the Royal Institute of British Architects; (2) a certificate of having

attended the second and third year's course, including the architectural studio course and the passing of the final examination at King's College, London, in lieu of Sections I., II. and III. of the Society's own examination; (3) a certificate of having attended the three years' course of the Glasgow and West of Scotland Technical College in the subjects of architecture, architectural design and building construction, and of having satisfactorily passed the final examination of the same institution in those subjects, as in lieu of Sections I. and II. of the Society's examination; (4) in lieu of Section I. of the Society's examination a certificate of having gained a first class in South Kensington examination in the subjects of architecture and architectural design, and as in lieu of Section II. of the Society's examination, a certificate of having obtained honours in the South Kensington examination in building construction, including the practical examination.

All applicants will also be required, as heretofore, to fill up the authorised nomination form and to be recommended for admission to the Society on the strength of their professional and personal qualifications, by at least two members of the Society.

THE SIGNIFICANCE OF GOTHIC.

AT the last meeting of the Literary and Philosophical Society of Leicester, the Rev. P. T. Forsyth, M.A., lectured on "The Significance of Gothic Architecture." He said that it inevitably happened in the course of a lecture on the subject he had selected that he would have to deal with religious ideas. He desired it to be understood that he did not deal with those ideas with respect to either their truth or falsehood. He had nothing to do with that. On this occasion he put off for the time the profession to which he belonged and he simply approached the subject from a historical point of view, as indicating that in structures there were certain ideas conveyed, and whether they were right or wrong he would not attempt to discuss. Architecture held a place between the arts practical and ideal, between utility on the one hand and beauty on the other. Its first purpose was to be useful, to provide common places of shelter or enclosure. It was a means, not an end in itself, and it was only in its later stages that it became an art in the true sense of the word, an end in itself, and an expression of the soul's delight. The church building was first of all a rendezvous and meeting-house, and only after centuries did it become a cathedral. When architecture was treated in connection with religion it meant, of course, the temple, and they asked what was there distinctive and beautiful about the Christian temple, how far was it a piece of art, how soon did it become so, and how far did it express the distinctive aims and forms of the faith, and how far did it differ from the most perfect pagan temple? The Christian temple of course was the cathedral, and this was not the outcome of a generation, but the building of a century and the outcome of 900 or 1,000 years of cumulative force. In the first three centuries of Christendom there were practically no churches. The Christians met in private dwellings, in lodges and in philosophical schools, and worse still, in caves and catacombs. This was due to two causes—first, the simplicity of the early Christian faith, which made a church of whatever place the members frequented; and, secondly, the persecution to which they were subjected. But it was another matter when this strange creed, buried alive, so to speak, hitherto, was brought forth not only into the light of day, but into "the fierce light which beats about a throne." With startling suddenness the Christian religion took its place upon the throne, and it became identified in some measure with the Roman State. It at once began to spread and organise the forces of the world. It adopted the form of the Roman basilicas, or courts of justice, for its churches, and as it developed and progressed this was transformed into the cross-like formation which had formed the ground-plan of future ecclesiastical architecture. Thus it unconsciously became a significant reflection of the great central idea of Christianity. This cross-like ground-plan was not adopted because it was a Christian symbol, but was the growth of requirements. From the third to the tenth century there was no perceptible advancement in the outer style of architecture, for though internally there might have been an increase in barbaric splendour the structure was still of the basilica type. From 1000 to 1200 they got the Romanesque period, the chief characteristic of which was the rounded arch. The exterior of the building began to receive more attention, the tower began to rise from the centre of the cross ground plan, suggestive of aspiration, and unity was expressed in the arch. In the thirteenth century they got the pointed arch, and this was a symbol of a grand change, furnishing, as it were, the organ for a combined outburst of beauty and genius. The Classical disappeared before the Gothic. The rounded arch was heavy and lowering, weak in the middle, bearing to excess upon the side walls, and requiring them to be of heavy construction. With

it it was impossible to express properly Christian aspirations of the lightness and beauty of religion, but with the leaf-like pointed arch they were able to obtain lightness and elegance of design, and all that made the beauty of the Gothic temple lay in this change. The great strength of this arch did away with the necessity for massive side walls with small windows, as the whole support of the roof could now be relegated to the pillars. The style of our cathedrals conveyed the idea that they were organic, springing naturally from the earth with a tendency heavenward. Then they were a miniature of the world, combining styles diametrically opposed to each other in themselves into one harmonious whole, and they also conveyed the Christian ideas of unity and sacrifice. Sacrifice was expressed in their every part, every part being subservient to the whole, and this unity produced an effect symbolical of the calm of Christianity—the solemn calm of progress in outward life, and an unresting desire for improvement in spiritual affairs.

WOODSIDE BATHS, HALIFAX.

THE following statement about Woodside Baths has been prepared by Messrs. Horsfall & Williams, the architects:—

Our attention has been called to the fact that the outlay on Woodside Baths was once again brought to the front at the Markets Inquiry as a case in point of architects exceeding their estimates. We have, so far, permitted statements of this kind, made by persons unacquainted with the truth, to pass without comment, simply because we did not think such statements worthy of notice, having confidence that our professional reputation (pardon the egotism) in this district for not only reliable estimating, but for carrying out the works entrusted to us without extras of any kind, rests on a much broader basis than that of Woodside Baths. However, that no person may have any excuse in the future for circulating stultifying suggestions regarding ourselves in connection with the Woodside estimates (in ignorance of the truth), we now break silence and place the facts before the public, leaving them to be the judges as to the unjustness of our critics and detractors.

When it was decided to erect baths at Woodside, the Corporation naturally looked out for a site possessing convenience of locality, selecting the one upon which the baths are now built. The site was purchased before we came on to the scene at all, so that we were in no way responsible either for its fitness or its costliness.

The Corporation decided to have a competition open to the architects of the borough, but before doing so propounded a scheme of their own so far as settling the size of the swimming-bath, and the number of slipper-baths for each class and sex. From this it will be seen that these particulars settled the size of the building.

The Corporation decided also that this building was to cost 5,000*l.*, thus themselves settling definitely the quality and finish of the work. A large building for small outlay, of course, means inexpensive and less substantial work, for no man can give eighteenpence for a shilling. With these conditions before us, we prepared designs, and as premiums were offered, sent in two sets of designs, and these had the honour of both being selected for premiums.

The Corporation admired certain points in both designs, and we received instructions to prepare a modified plan embodying all the good features of both. Our estimate for the amended scheme for the same class of work was 5,990*l.* 19*s.* 3*d.*, and the actual cost of carrying out the same, exclusive of the additions made by the committee, and the unforeseen exigencies of the site, was 5,903*l.* 11*s.* 3*d.*, or 87*l.* 8*s.* less than our estimate.

We now had instructions to prepare builders' plans and specifications, and as is always our rule, employed men to dig trial holes on the site, that we might ascertain the nature of foundations. We now made the alarming discovery that the ground for a considerable depth consisted of loose filled material, and we were informed by men who knew that an extensive bed of clay had been removed many years ago. We felt it our duty at once to report the matter to the committee before proceeding further with the plans, the state of things indicating the necessity of foundations 12 and 14 feet below the turf, and also a strong sheeting of cement concrete over the whole of the site of the large bath chamber. After due deliberation, in consequence of the difficulty of obtaining suitable sites in the neighbourhood, and the fact that the Corporation had this one on their hands, it was decided to still proceed with the work. This unforeseen item caused an outlay to be involved of 749*l.* 3*s.* 6*d.* for extra foundations.

It was also finally decided to set back the building to permit of the future widening of Haley Hill, and as the levels of site fell rapidly from the road, to do this and still preserve the possibility of drainage into Haley Hill the level of the whole of building had to be still kept up to the same level, involving a

foot of extra height of walling throughout the whole structure and the same thickness of cement concrete over the whole of the bath chamber, at a cost of 166*l.* 5*s.* This brings the total cost of the scheme on the original lines up to 6,818*l.* 19*s.* 9*d.*

In going into specification details, the committee, seeing that the original amount fixed by them was insufficient for the most substantial and durable of fittings and furnishings, very wisely decided to spend a little more money in improvements and do the work in the best possible manner, being the cheapest in the end, and we beg leave to state that every penny of increase so involved was money well spent and for the public good. Under this category comes the "all steel roof," wood boarding instead of plaster, a special hard brand of hand-made bricks for lining the large bath-chamber, lining swimming-bath throughout with solid glazed bricks instead of tiles, all improvements being of this class. The total cost of all such matters being 1,020*l.* 2*s.* 6*d.*, and as our final certificates for all contracts passing through our hands was for 7,839*l.* 2*s.* 3*d.*, it will be seen that we carried out the work without a penny extra incurred by ourselves.

MANCHESTER CORPORATION SCHEMES.

AN inquiry has been held at the Manchester Town Hall by Colonel A. G. Durnford, R.E., an inspector of the Local Government Board, into applications of the City Council to borrow the following sums:—100,000*l.* for electric-lighting purposes, 100,000*l.* for works of sewerage and sewage disposal, 50,000*l.* for purposes of the Technical Instruction Act, 10,000*l.* for works of paving, 1,500*l.* for the provision of a pleasure-ground at Ancoats, 300*l.* for public baths, and 300*l.* for a public room.

Mr. Alderman Hoy, chairman of the Technical Institution committee, detailed the circumstances which led up to the erection of the Technical School. The Whitworth legatees, in handing over to the Corporation the Technical School and the Manchester School of Art, together with a certain sum in money, gave them also a plot of land in Whitworth Street on which to erect the Technical School. The committee asked for competitive plans for the new school. Mr. Alfred Waterhouse was called in to assist the committee to decide on the best plans. Under his advice the designs of Messrs. Spalding & Cross, of London, were selected. The next thing done by the committee was the giving of an instruction to Mr. Windsor, quantity surveyor, to make an independent statement of quantities. The committee had originally sought to borrow the sum of 150,000*l.*, which they had regarded as sufficient for the purpose of building and equipment. But the committee made many suggestions as to alterations of the plans and the substitution of materials. Mr. Windsor estimated that the cost of the school had by the adoption of these suggestions been increased by 29,377*l.* The estimate of Messrs. Spalding & Cross was that their plans might be carried out for 85,000*l.* The lowest tender, that of Messrs. R. Neill & Sons, of Manchester, was 133,950*l.*, with an alternative tender of 141,000*l.* Mr. Alderman Hoy described the work carried on at present in the schools handed over to the Corporation by the Whitworth legatees, and explained what were the resources of the Corporation.

THE SANDEMAN LIBRARY, PERTH.

THE new public library in Perth, which is to be erected from the designs of Messrs. Campbell, Douglas & Morrison, of Glasgow, will have public and private entrances in the new street facing the east. The reading-room is placed at the north end, with its side facing Mill Street, in which there are two large bow windows; the juvenile department is placed as an annexe, and adjoins the vestibule and hall. The lending library is at the south end. Its ceiling has been made 2 feet higher than that of the reading-room in order to make up for the sills of the window being necessarily kept high on account of the book-shelves. The ceiling heights of the principal rooms are as follow:—Reference library, 18 feet to the top of the cornice, average height in coved ceiling 21 feet 6 inches; museum, average height, 20 feet 6 inches; reading-room, 15 feet 6 inches; lending library, 17 feet 6 inches; librarian's house, 11 feet; basement, 7 feet 3 inches. The museum or hall is placed over the librarian's house at the south end of the building, and is lighted principally from the roof. It is intended to finish the side walls with a curved surface for the better exhibition of whatever is hung thereon. Although the museum is conveniently placed and groups well with the rest of the design, it can be omitted, the whole building being two storeys throughout. In every part and for every purpose the windows are so designed and placed that the maximum of light falls on all desks, tables and book-shelves wherever possible, and in a way that will prove efficient, as experience has shown. Externally the style of architecture is simple Italian Renaissance, permitting a large

number of windows. In the roof of the reference library and museum the principals are of wrought-iron, and the openings to the inner skylights are slightly sloped in the sides so as to give a wider distribution of light than parallel sides would admit of. The library staff need not be large, as it may be effectively worked in all its departments by a librarian and four assistants. The chief entrance is in the centre of the new street. Advantage has been taken of the large ventilator over the reference library to suggest a suitable place for a clock, which, it is thought, would be a convenience to the neighbourhood, and which, it has been ascertained, is perfectly compatible with a good system of extracting the vitiated air. The principal constructive materials proposed to be used are chiefly as follows:—One of the Dumfriesshire red stones, and externally all ashlar will be cross-hewn where not polished; the general finishings to be of the best quality of yellow pine, and the book-shelves to be of Kauri pine, or other hard wood, polished. As the roofs are not very steep, and the building is finished with cornice and parapet or balustrade, the roofs will not attract much notice till one is 30 or 40 yards away from the building, and it is therefore proposed to use good Ballachulish or old Easdale slates. For fireproof construction the system proposed to be used is that known as Fawcett's, with which the designers have been well pleased. It is proposed to tile the lower walls of the general reading-room and juvenile department. The heating suggested is by means of low-pressure hot-water pipes, combined with the admission of an ample supply of fresh air. The vitiated air will be extracted by means of ventilating shafts leading to patent exhaust ventilators on the roof. The cubic contents have been ascertained by measuring from the bottom of the foundations to one-half the height of roof, the total quantity being 334,600 cubic feet (exclusive of museum). The rate per cubic foot has been arrived at from the actual cost of buildings recently erected and of a somewhat similar character to the present building, inclusive of lighting, heating, ventilation, interior fittings and plain painting. Cubic contents—334,600 cubic feet at 6½*d.*, 9,410*l.*; add fees 6½ per cent., 588*l.*—9,998*l.* To complete the design, including the museum, the extra cost would be as follows:—49,200 cubic feet at 6½*d.*, 1,383*l.*; fees at 6½ per cent., 87*l.*—1,470*l.*

GENERAL.

Mr. C. J. Ferguson, architect, of Carlisle, is about to start for Athens to make an investigation into the damage done to the Parthenon by the recent earthquake.

A Design by Mr. C. B. Fowler, of Cardiff, has been adopted for the public fountain which is to be erected by Mr. Thomas, M.P., in Pontypridd.

The Jasper Vase ordered by the late Emperor of Russia for presentation to the city of Paris is now complete. It is cut out of a block from the Caucasus.

Dr. Marjolin, who died in Paris on the 7th inst., has left a sum of 4,000*l.* to the French Académie des Beaux-Arts, the interest on which will be given every second year to the French artist who has produced the best engraving in "taille-douce."

A Hippodrome with an area of 12,300 mètres is about to be constructed on the Boulevard Malesherbes, Paris, from the designs of M. Yvon.

The Officers elected at the annual meeting of the Northern Architectural Society on the 20th inst. are as follows:—President, Mr. J. Oswald; vice-president, Mr. F. W. Rich; honorary secretary, Mr. A. B. Plummer; honorary treasurer, Mr. J. T. Cackett; honorary librarian, Mr. H. C. Charlewood; council, Messrs. C. F. Armstrong, F. E. Caws, W. Glover, W. S. Hicks, J. H. Morton (ex-officio), and J. W. Taylor; Mr. R. B. Dick and Mr. C. S. Errington.

A Paper on "Forestry" will be read at the ordinary general meeting of the Surveyors' Institution on Monday next, by Mr. G. Cadell.

A Large Stained-Glass Memorial Window has been publicly unveiled in St. John's Church, Bethnal Green. It is erected to the memory of the late Mr. Keymer, of Whitefriars Street, E.C., superintendent of Sunday schools, the subject chosen being *Our Lord Blessing Children*. The window was erected by Messrs. Alex. Gibbs & Co., 10 Bloomsbury Street London, W.C.

Messrs. Amos & Foad have been declared the contractors for the New Ashford board schools, of which Mr. H. J. Jeffrey is architect.

Mr. Edward Hargitt, one of the members of the Royal Institute of Painters in Water-Colours, died recently. His pictures of English rural scenery were marked by their quiet simplicity. Mr. Hargitt was also an enthusiastic and competent ornithologist. He lived long enough to complete his great monograph on the woodpeckers for the British Museum, a labour of love on which he had been engaged during the past twelve years.

The Architect.

THE WEEK.

THERE are so many pictures in the South Kensington Museum by modern English artists that works by the old masters appear to be out of place in the galleries. On the other hand, water-colour drawings are not appreciated as they merit when seen in the National Gallery. It is, therefore, satisfactory to learn that a sort of temporary exchange of works between the two institutions has been arranged. The National Gallery will lend a collection of water-colour drawings by DE WINT and CATTERMOLLE, and some sketches by TURNER. From South Kensington pictures will be sent to Trafalgar Square, including a large fresco by PIETRO PERUGINO and a head of St. PETER MARTYR, by GIOVANNI BELLINI.

IF light railways can help English agriculturists and country traders to overcome some of the difficulties which are now oppressive, as many facilities as possible should be given for their construction. But the precedents observed with ordinary railways should be set aside. A system which enriches lawyers and Parliamentary agents at the expense of shareholders is a scandal. A paper was read by Mr. McLAREN before the Farmers' Club on Monday in which he explained the procedure which should be followed, as well as that which should be avoided. His propositions were as follows:—(1) That in many parts of the country light railways would be a great advantage. (2) That the present hindrances, mainly due to the stringent requirements of the Board of Trade, should be relaxed, so as to admit of the construction and working of light railways without the expenditure of unnecessary capital. (3) That new powers should be given to the Board of Trade to authorise the construction of light lines, either alongside of public roads or otherwise, granting compulsory powers to take land, and in case of dispute to appoint an arbitrator or valuer to finally and promptly decide between the parties. (4) That the procedure should be simplified so that the expense of obtaining the necessary powers should not, except in extraordinary cases, exceed 25% per mile. (5) That all light railways should be of the standard 4 feet 8½ inches gauge. (6) That wherever it can be arranged they should be worked by the railway company with whose line they communicate. (7) That the decision of the District Councils shall be *prima facie* evidence as to whether the lines are required or not. (8) That the District Councils shall have power to guarantee a dividend of not more than 3 per cent. per annum on the capital invested in the construction of the line. Mr. McLAREN's proposals have much to recommend them. What is required is an imitation of American practice. An English railway is made as if it were to endure for eternity. But changes are inevitable. Lines have to be widened, bridges altered, platforms lengthened. The excellence of the work increases the expense of alterations, and the shareholders have to pay for things that are profitless. If a similar rule were imposed on American engineers a great part of the country would still be in its primeval condition. They are moderate in their expenditure until adequate profits come in, while in England it is imagined that the costliest work can be met by the traffic, and in consequence a perennial source of loss is often created.

AT one time in Ireland the word valuer was as comprehensive as 'civil engineer or architect,' and it was employed by gentlemen who were not distinguished by their knowledge of the subjects it represents. The existence of a Government department that regularly determined the value of the smallest holdings facilitated the creation of would-be experts. Many a time large sums have been paid for valuations which were ascertained by merely adding a nearly uniform percentage to the amounts entered in the valuation lists that were prepared for the purposes of taxation. In consequence larger sums have been given for estates than they were worth, and unhappy relations between landlords and tenants sometimes owe their origin to that cause. The anecdote related by Mr. CARSON, Q.C., in the debate on the Land Law Bill on Tuesday, reveals

how unscientific and baseless is the process which still passes for valuation in Ireland. It is so amusing, and at the same time so characteristic of Irish business as to be worth reprinting:—"They told the right hon. gentleman," said Mr. CARSON, "that the question of fair rent was a question of valuation; it might differ according to the men who made the valuation. Once they put an end to the free contract as between landlord and tenant they were always driven back to those absurdities, that the rent to be a fair rent would be held by one valuer to be 10% and by another 30%, according to the predilections of each individual. While valuers differed sometimes, it was alleged occasionally that in making an independent valuation they had arrived at the same conclusion as regarded fair rent. He recalled one case in this connection. Two valuers were called up, one after the other, to value a farm. One of the valuers valued the farm at 59% 19s. 11½d. Another gentleman who was called up said that he had valued the farm exactly at the same figure. On further examination this gentleman said that he had not communicated in any way with the previous valuer, and that he had made his valuation from field to field, and without having seen the result brought out by the previous witness. In cross-examination the witness told the Court that he had great experience in valuation work, and that he had taken charge of many difficult cases. Then the witness was asked this question by counsel, 'May I ask whether you happened to see on any part of the farm "a coincidence?"' Turning over the leaves of his note-book, he replied, 'Yes, I think in one of the fields, near a far corner, there was one, but I do not know that I paid particular attention to it.'" It is no wonder the House of Commons laughed at the story. Can anyone expect that agrarian disputes will come to an end when land is valued in such a haphazard fashion? If some Irish Secretary could persuade a few of the English surveyors to accept office in Ireland in order to establish a proper system of valuing land an immense benefit would be conferred on the country.

THE paper read by Mr. W. R. WATSON at the meeting of the Glasgow Architectural Association on Tuesday was upon Sir CHRISTOPHER WREN. He gave an historical and descriptive account of England in the middle of the seventeenth century, and explained the state of general science and the architectural practice of the period. The chief events of WREN's interesting and eventful career were then alluded to, notably the visit to Paris, and it was shown under what advantageous circumstances that visit was made. Referring to the circumstance that WREN, unknown even as an architectural amateur, was selected to assist the Surveyor-General, the lecturer remarked that he was at that time, more than any other man in the kingdom, equal to anything of national importance that might be required. His love for architecture was only a part of his sympathy for everything that could appeal to a man of genius; had there been no mathematician of eminence besides himself, nor any remarkable poet, painter or sculptor, WREN would have been all or any of these, as the necessity of the time might have required. The second part of the paper was devoted to a description of a few of the great architect's better known works, and was illustrated by diagrams, photographs, &c.

THE London School Board evidently consider that their organisation is perfection, and, if an error should arise, it must be through some defect outside the offices on the Embankment. Recently tenders were solicited for a school for 800 children at Tooting. Messrs. GREGAR & SON, who were one of the selected firms, in sending in their tender stated that three of the bills of quantities were not supplied to them, viz. the preliminary bill and the bills for extra depth of foundations and for building the brickwork in cement, and that no provision for these bills was made in the amount of their tender, which amounted to 18,756%. The works committee appear to have treated the lapse as a fault of the contractors, and another tender was accepted. The question, however, must be asked, why should Messrs. GREGAR & SON be set aside through some failure on the part either of the School Board officials or of the Post Office?

MODERN GERMAN ARCHITECTURE.*

ALL the world has read (for THACKERAY was the historian) about the famous fight between the booby WILLIAM DOBBIN, the "gee-ho" of Dr. SWISHTAIL'S Academy, and Master CUFF, who was the head boy and dandy. They know how all the youths were amazed when the Cock of the School succumbed after thirteen rounds. DOBBIN'S unexpected victory transformed him. He gained self-confidence, and although his Latin poetry was never brilliant, he was so successful in mathematics that a copy of "Telemachus" was presented to him at the end of the term. Afterwards he turned out to be a brave and modest soldier. The Germans have had a like fortune. They were supposed by the rest of Europe to be the most impracticable of mortals, fit only to reside in that cloudland which HEINE assigned to them in his partition of the universe. DOBBIN would probably have remained a booby all his life if he had not spoiled the countenance of the king of the school. The estranged races of Germany would likewise have endeavoured to content themselves in the fog-lands of metaphysics and other unrealities if they had not found that they could use swords as well as make verses about them. Members of the Peace Society were shocked when, a few days ago, the Emperor, in presenting a sabre to his ex-Chancellor, spoke like an ancient warrior. They should remember that what Germany gained by fighting was infinitely more valuable than the winning back of some land and water and milliards of francs. Self-respect was achieved and a conviction of the possession of power, and they are worth any price. No longer content with abstractions, the Germans since their wars have become the rivals of Englishmen and Americans in utilising the materials which nature affords, and the science which formerly held a position not unlike that of poetry has become the inspirer of the manufacturer.

As a consequence there is a vast change in German books. They no longer go back to the origin of things in the search for a metaphysical basis of a subject. War has taught the authors that we are here to grapple with realities, or what pass for such, and they are accordingly sought out with a sort of fervour. The address of Professor BROCKHAUS is an example. Who could have believed thirty years ago that in the University of Leipzig, a city that seems to have books instead of piles for its foundations, the subject of architecture would be treated without any reference to the theories of the art which have there originated, and that the word "ästhetisch" would be rarely used in the discourse? But who could have imagined thirty years ago that the market-place would be one day dominated by a colossal group of the five directors of the overthrow of France? They also triumphed over the old systems which were constructed in Leipzig, for as long as students gaze on the figures of the Emperor, his son and nephew, BISMARCK and MOLTKE, they must be convinced that abstractions are not fitted for conquest in this world. Another sort of spirit is also manifest in the address. Every German must now feel that the world lies open to him. Professor BROCKHAUS accordingly looks on the architecture of the past as a treasury which can be used. In England and elsewhere that sort of belief is not unknown, but the past is utilised in an almost shame-faced manner, as if a sort of petty larceny was being committed in imitating ancient forms. A third peculiarity also deserves to be mentioned. Professor BROCKHAUS is not afraid to refer to buildings designed by his countrymen who are still living, and to praise them with heartiness.

In the beginning of his lecture the Professor refers to the national spirit which made Gothic the favourite style for Lutheran as well as for Catholic churches. The so-called Jesuit style found no favour with German congregations, but in modern buildings for the Lutherans Mediæval plans have not been faithfully adopted. The Lutheran ritual has of late dictated the plan. Of course, Professor BROCKHAUS was not satirical when he takes up the subjects of theatres immediately after churches. He speaks with admiration of the new theatre in Leipzig, which is an effective building. But like so many who restrict architecture to exteriors, he does not say a word about the

interior arrangements, which are successful in enabling an audience to hear and see with comfort. Few German theatres are more satisfactory for a playgoer. The new concert-hall in Leipzig is also a remarkable building and in some ways unique. The Professor is not afraid to render justice to the Parliament House in Berlin, which has not received the approval of the Emperor, and he couples with it the new Law Courts in Leipzig. In describing those buildings, he recognises the influence of SCHINKEL in the Gothic as in the Renaissance manner. There is also a tribute of praise given to the Law Courts in Brussels, a group of buildings from which continental architects have drawn much inspiration.

The Professor then considers the materials for construction. Stone is not easily obtainable in all parts of Germany, but its use for erecting sumptuous buildings is recognised, and it is thus employed in Munich, Dresden and Berlin. For official buildings it is appropriate, but its use in Germany is a testimony of costliness. Brick has stronger rights to be recognised as the national material. SCHINKEL used it in the Werder'sche Church, near the palace in Berlin, as well as in the Academy of Building. In Hanover it has been a favourite material with architects, but in the majority of German cities brick buildings form an important element. In a warrior nation iron must command respect. Professor BROCKHAUS could hardly express more admiration for it if he were addressing a class of engineering students. He points out that without it modern necessities could not be satisfied. He compares old and new railway stations, old and new markets, in order to show what is gained by its adoption. Then there are exhibition buildings, like the Crystal Palace in Munich, which exist because iron beams and columns could be utilised for the construction. In the last-named building about 2,000 works can be exhibited every year, which attract 100,000 visitors. In a city like Munich, which is not over wealthy, it is an advantage for artists to have a building where their works can be well seen and visited without inconvenience. That is not the only use of iron which the Professor recognises. Purists and theorists will object when they find that he admires its employment as a sort of skeleton which can be clothed with materials of other sorts. The dome of the Law Courts in Leipzig and the roof of the Hall of Assembly in the Berlin Parliament House are examples of its subserviency to architectural necessities. It is worth noting that the Professor admits the indebtedness of builders to the exhibition building of 1851 in Hyde Park as a demonstration of what could be done with iron as the principal building material.

In considering the personal influence of the architect the Professor goes back to the last century. In noticing the career of J. B. FISCHER a few weeks ago, we explained his admiration for the Baroque style of Italy. As all German rulers aped LOUIS XIV., a sort of combination of that style with French became popular in most parts of Germany. It was unfashionable to imitate old German work, but a class of men arose corresponding with the poets who declined to follow French models in literature, and they believed that the earth presented before men's eyes no more beautiful buildings than the Mediæval temples in Strasburg and Cologne. GOETHE, however, while admiring Gothic was captivated by Italian architecture. He found a great many imitators even among architects. The tendency of German taste oscillated between north and south. The discoveries of Scandinavian literature naturally compelled men to feel that they were allied to the Vikings, and that their style of building should be Gothic. On the other hand, the love of the classics made them admire Greek and Italian work. SCHINKEL and SEMPER represented the latter, HEIDELOFF the former. Men who might be supposed to be impartial, who were critics rather than builders, were found on both sides, and when JACOB BURCKHARDT taxed the Mediævalists with ingratitude for forgetting their debt to the Italians, he was met with assertions as strong about the opposite view of duty. The varieties of opinion are exemplified in Munich more than in any other German city with which we are acquainted; all styles are congregated in the streets. But Berlin also is not without exotic examples, which become more striking from their contrast with the military precision of the majority of the buildings.

* Unsere heutige Baukunst Antrittsvorlesung: gehalten am 9. Februar, von Dr. Heinrich Brockhaus. Leipzig: F. A. Brockhaus.

The facilities for travel and the ease with which photographs of buildings can be taken provide a stock of information for students such as would be deemed impossible in an earlier age. How is it to be used? In spite of the hold which Mediæval buildings have had on the German mind, Professor BROCKHAUS perceives that the fascination of the South is still more strong. Classic and Renaissance has the advantage of allowing the employment of sculpture of the highest class, while with Gothic figures must be distorted. The caryatides seen on one of the façades of the new Leipzig theatre are a sort of decoration which cannot be easily surpassed. Similar figures have been employed in other German buildings and they always meet with admiration. In a country where there are many able sculptors who are competent to produce fine figures at a moderate price, the style of building that seems to be most eligible is one in which sculpture can be largely utilised. But Professor BROCKHAUS does not rely on that sort of adornment alone. He realises that science can produce coloured materials, that terra-cotta can be cheaply purchased, and in many ways structural forms can be enhanced by decoration. In other words, he accepts the world as it is, and he sees no reason for a man in the nineteenth century to long after existence in an earlier period of art. The German architect, he perceives, has manifold resources, and it will be his own fault if he does not employ them for the benefit of his contemporaries.

POMPEII.*

THE ruins of Pompeii, ever since their discovery by Don ROCCO ALCUBIERRE in 1748, have enlisted a great amount of interest from their importance in revealing to the nineteenth the conditions of the life of the inhabitants of a Roman city in the first century. Nothing, perhaps, could be more conducive to the continuance of that interest than the gradual and slow uncovering of these ruins that has been in progress during the last fourteen years, for fresh objects are brought to light, and so successive stimuli are given to the public who desire to know more.
